The increase during the year in the lamp connections of close on 40 per cent., which has already been referred to, created a record in this respect, compared with any previous year in the history of the concern, as the table given below shows. Many of the lamps were, however, only connected towards the end of the year, so that the benefit accruing from them is not to be looked for till this current year. Other reasons for the small comparative increase in the output are a very light season and the absence of the usual November fogs, combined with the fact that the contractor's account for current on the local electric railway was £650 less than in 1897. The Company are to be congratulated on recognising the necessity of reducing their tariff for current. It is proposed to reduce the price charged per unit supplied at 200 volts' pressure from 6d. to 5d. More than two-thirds of the consumers are being supplied at the higher pressure of 200 volts.

Year.	No. of consumers.	Equiv. 8 c.p. lamp connection.	Units sold.	Revenue (total).	Working profit.	Total costs per unit sold.	Ord. div.
1891	77	6,056	30,162	£1,623	– £555	17·34d.	nil
1892	124	9,438	75,667	3,513	+ 112	10·78d.	nil
1893	173	12,153	107,580	4,329	+ 1,481	6·355d.	nil
1894	234	15,669	130,266	5,123	+ 2,102	5·565d.	1%
1895	307	20,307	182,327	6,940	+ 3,228	4·885d.	2%
1896	396	25,716	230,787	8,552	+ 4,736	3·966d.	4%
1897	571	33,000	354,969	11,626	+ 6,854	3·220d.	6%
1898	788	46,066	455,871	13,418	+ 7,252	3·247d.	6%

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Aberdeen (Municipal)	1899	Jan. 6	
Ayr (Municipal)	1898	Nov. 11	
Bedford (Municipal)	,,	Mar. 4	
Belfast (Municipal)	,,	Sept. 23	
Birmingham (Company)	,,	Dec. 16	
Blackpool (Municipal)	,,	Oct. 7	
Bournemouth (Company)	,,	June 3	
Bolton (Municipal)	,,	Dec. 9	
Bradford (Municipal)	,,	May 20	
Brighton (Municipal)	,,	May 6	
Bristol (Municipal)	,,	July 29	
Burnley (Municipal)	,,	Sept. 16	
Burton-upon-Trent (Mun.)	,,	April 15	
Bury (Municipal)	,,	Nov. 25	
Cambridge (Company)	1899	Mar. 10	
Cardiff (Municipal)	,,	Jan. 6	
Charing Cross (Company)	1898	April 22	
Chelsea (Company)	,,	May 20	
Cheltenham (Municipal)	,,	Oct. 7	
Chester (Municipal)	,,	Oct. 14	
Clerkenwell (Company)	,,	Mar. 18	
Derby (Municipal)	,,	Dec. 9	
Dewsbury (Municipal)	,,	Nov. 25	
Dover (Company)	,,	Mar. 11	
Dundee (Municipal)	,,	Nov. 4	
Eastbourne (Company)	,,	July 22	
Edinburgh (Municipal)	,,	Oct. 14	
Exeter (Municipal)	,,	Aug. 5	
Glasgow (Municipal)	,,	Aug. 12	
Guildford (Company)	,,	May 13	
Halifax (Municipal)	,,	Nov. 18	
Hammersmith (Vestry)	,,	June 10	
Hampstead (Municipal)	,,	Sept. 9	
Hanley (Municipal)	,,	April 8	
Harrogate (Municipal)	,,	Dec. 30	
Harrow (Company)	,,	Sept. 9	
Hast'gs & St. Leonard's (Co.)	,,	April 29	
House-to-House Co. (K'ns'gt'n)	,,	Sept. 30	
Hove (Company)	1899	Mar. 10	
Huddersfield (Municipal)	1898	Mar. 25	
Islington (Vestry)	,,	June 24	
Kens'gton & Knightsbr' (Co.)	'99	Mar. 3	
Kingston-upon-Hull (Mun.)	1898	Aug. 19	
Kingston-on-Thames (Mun.)	,,	Mar. 25	
Lancaster (Municipal)	,,	Oct. 21	
Leeds (Company)	1899	Mar. 3	
Leicester (Municipal)	,,	Jan. 20	
Leyton (Municipal)	1898	Sept. 23	
Liverpool (Municipal)	,,	Aug. 12	
Manchester (Municipal)	,,	July 29	
Newcastle and District (Co.)	,,	Dec. 2	
Newcastle-upon-Tyne (Co.)	,,	April 29	
Northampton (Company)	,,	April 15	
Norwich (Company)	,,	Dec. 2	
Notting Hill (Company)	,,	Mar. 11	
Nottingham (Municipal)	,,	Oct. 28	
Oldham (Municipal)	,,	Nov. 18	
Oxford (Company)	,,	April 1	
Portsmouth (Municipal)	,,	Nov. 4	
Preston (Company)	,,	Oct. 28	
Reading (Company)	,,	Sept. 16	
Richmond (Company)	,,	Mar. 4	
Scarborough (Company)	,,	April 1	
St. James' & Pall Mall (Co.)	1899	Feb. 24	
St. Pancras (Vestry)	1898	May 13	
Sheffield (Company)	,,	Dec. 16	
Shoreditch (Vestry)	,,	May 27	
Southampton (Municipal)	,,	June 3	
Southport (Municipal)	,,	Dec. 23	
Stafford (Municipal)	,,	Oct. 21	
Sunderland (Municipal)	,,	Aug. 19	
Taunton (Municipal)	,,	Aug. 5	
Tunbridge Wells (Mun.)	,,	July 22	
Walsall (Municipal)	,,	Nov. 11	
Wandsworth (Company)	,,	Mar. 18	
Westminster (Company)	1899	Feb. 24	
Whitehaven (Municipal)	1898	Dec. 23	
Windsor (Company)	,,	Dec. 30	
Wolverhampton (Municipal)	,,	July 15	
Woolwich (Company)	1899	Jan. 13	
Worcester (Municipal)	1898	May 13	
Yarmouth (Municipal	,,	June 17

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON,

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician" Printing and Publishing Company, Limited, and be crossed "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" commence in April and October.

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" Printing and Publishing Company, Limited. The well-known "Electrician" Series of Standard Electrical Works at present consists of—

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. R. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particulars on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I.** Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations. price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gnipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 3d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 6d., post free, 8½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 2s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

HERTZIAN TELEGRAPHY.

Wireless telegraphy of the sort involving the action of Hertzian ether waves upon a coherer has occupied the attention of the Institution of Electrical Engineers during its last two or three meetings, and, incidentally, has provided for members and their friends an unusually sensational programme. It is too early yet, especially in view of the fact that Mrs. Ayrton has yet to read her Paper on the electric arc, to say that the reception of Mr. Marconi's Paper is the most brilliant feature of the session; but we can assert that nothing approaching it has occurred in the history of the Institution, not even excepting the memorable occasion when Nikola Tesla gave his lecture in the theatre of the Royal Institution. Yesterday's overflow meeting at Exeter Hall, when Mr. Marconi repeated his discourse, was an event absolutely unique in the annals of the Institution of Electrical Engineers. A much smaller room had originally been acquired for the purpose; but ere members had had for 24 hours an opportunity to ask for tickets, the number of applications was overwhelmingly greater than the accommodation arranged for; so that quite late on Thursday in last week, as we announced in our last issue, the Council was compelled to engage the Lower Exeter Hall, the larger dimensions of which even fell short of sufficiency.

Whether wireless telegraphy as a practical art will be advanced by recent proceedings of the Institution remains to be seen. A Paper, mainly in the form of a popular narrative of what was already known, followed by a discussion largely interrogatory and speculative, can only effect a practical advance through secondary and indirect issues; Mr. Marconi himself is not likely to have received therefrom any new inspiration; and members thirsting for knowledge have been left to obtain it from a reconsideration, possibly in a new light, of facts previously published. As we write this we are in ignorance of the nature of Mr. Marconi's reply, which he promised to make last night; and if he gave detailed answers to one half of the questions put to him during the discussion, it is scarcely possible but that some new fact of importance has been added to the stock of common know-

Digitized by Google

ledge on this fascinating branch of telegraphic science. Nevertheless, even if we have gleaned nothing absolutely novel, it has been a distinct gain to have had this Paper and its discussion: for ascertained facts and principles have thereby been ranged in a more logical and orderly fashion, and speculative hypotheses have had a chance of being tried, though in some cases at the risk of being found wanting.

Dealing, first, with the practical questions that arose in the discussion, and leaving matters of theory until afterwards, we may first notice the able speech of Mr. JOHN GAVEY, a lucid and business-like exposition of the experience thus far acquired by the Post Office. The law of the product of the heights—sometimes called the square of the height, owing to poles of the same height being used at the two stations—had been confirmed, and an essential difference had been discovered between land and sea telegraphy, the greater facility in the latter case being attributed to plane reflection from the surface of the water. At the receiving end a capacity might be substituted for the earth connection, without diminishing the effect, but at the transmitting end an earth connection was essential to good signalling. Reflectors had at first given satisfactory results, but on extending their application the effect was not so good; nevertheless, although reflectors had been abandoned, Mr. GAVEY saw great advantages in endeavouring to apply them successfully, as they would allow of a directive rather than a diffusive action between two or more stations.

A propos of the earth connection, the question asked by Mr. SULLIVAN as to whether or not the Marconi system requires an earth of little or no resistance is one of great importance in such cases as communicating with outlying and practically non-conducting rocks, such as the Fastnet. The conduction system, which was installed at the Fastnet some time ago, involves the employment of two submerged earth plates of low resistance at the rock itself, and, as will be remembered from Mr. GRANVILLE'S recent interesting remarks before the Institution, notwithstanding every possible precaution and care in submerging and securing these earth plates, communication has from time to time been interrupted in stormy weather through the plates being thrown up on the rock by the violent action of the sea. If the Fastnet and the numerous other rocks of a similar nature offer in themselves sufficient earth conduction for Mr. MARCONI'S system, thus doing away with the necessity of submerging earth plates, it would seem that he has solved the problem of establishing and maintaining in all weathers a reliable system of communicating with lighthouses on rocks under the severest possible conditions. Amongst other places where difficulty has been experienced in finding a sufficiently good earth for telegraphic purposes, Valentia, on the coast of Ireland, and parts of Nova Scotia and Newfoundland may be mentioned. All these have given trouble in submarine telegraphic working owing to their geological formation and non-conducting nature.

Theorists will find food for thought and, in some cases, for amusement in the speculations advanced to explain various aspects of wireless telegraphy as practised by Mr. MARCONI. Dr. ERSKINE MURRAY ventured upon an hypothesis of "discharge from fine points," and adopted an analogy between the vertical transmitter rod and the points on the prime conductor of a frictional electricity machine. Mr. MERVYN O'GORMAN declined to believe that Hertzian ether waves were essential, and advanced a theory that the Marconi telegraph could be worked by electrical currents oscillating through the earth between the two stations. We are not impressed with the necessity for any such hypotheses as the above, nor do we regard either as having the least degree of probability. Prof. SILVANUS THOMPSON'S optical analogy between reflection from a plane mirror and the effect of earthing MARCONI'S vertical wire requires support both from theory and from practice before it can be accepted as more than a pretty—but fanciful—illustration. In the first place the logical nexus seems to be wanting: we do not perceive the link between (1) a plane mirror reflecting an end-on stick in contact with it, (2) a slab of iron in end-on contact with a bar magnet, and (3) the Marconi wire perpendicular to the earth's surface. But even were there an *à priori* similarity of action in these three cases, it would still be necessary to show that earthing the Marconi wire really *doubles* its virtual length. It is insufficient to show that the earth intensifies the action; the effect, if the analogy is to hold, must absolutely follow the law of lengths found to be applicable to vertical wires. We fail to discover that it does so.

Telegraphic practice and theory, in times to come, will probably look back upon Mr. MARCONI'S Paper and its discussion as marking an important point in the history of wireless telegraphy—important, that is to say, in the same sense that a pillar of stone acquires importance when it becomes a landmark or a milestone.

OBITUARY.

DOUGLAS GALTON.

We announce with great regret the death of Sir Douglas Galton, K.C.B., which took place on Friday afternoon last, at his town residence, 12, Chester-street, S.W. By electrical scientists and engineers Sir Douglas Galton will be chiefly remembered on account of his active association with numerous scientific societies and committees thereof, and especially in connection with his secretaryship to the British Association, from 1874 to 1895, and his presidency of that Association in the last-named year.

Douglas Galton was born in 1822 and was educated at the Royal Military College, Woolwich, receiving a commission in the Royal Engineers in 1840. One of his earliest associations with electricity was in connection with the removal of the wreckage of the "Royal George" in 1842, when electricity was used for firing the charges of powder. A more important service to electrical enterprise, however, is found in his association with the development of submarine telegraphy; for, at the time when this important branch of telegraphy was decidedly under a cloud, viz., after the breakdown of the 1858 Atlantic cable, and when the Red Sea and Indian telegraph had proved a failure, Sir Douglas Galton was appointed chairman of the Special Committee of Parliament, formed to investigate the whole question of submarine cable enterprise. Between Dec. 1, 1859, and Sept. 4, 1860, 22 sittings were held, with the result that in 1861 a report was published which has been characterised as the "most valuable collection of facts, warnings and evidence ever compiled concerning submarine cables." In consequence of this report, further proceedings in the Red Sea were abandoned, and a section of the cable, already constructed but not laid, was successfully put down between Malta and Alexandria. Sir Douglas was also a member of the consultative committee (of which Lord Kelvin is now the only survivor) appointed to advise the Atlantic Telegraph Co. on the electrical and mechanical questions connected with the projected cable of 1865.

Although thus prominently connected with an important department of electrical engineering, Sir Douglas Galton's principal associations with engineering are to be found in his relations with sanitary science and practice, and also, to some extent, with railway commissions. As a sanitary scientist he was regarded as a high authority, while his services to railway engineering include the secretaryship to the Railway Commission, in 1847, appointed to investigate the application of iron to railway structures; also an inspectorship of railways, and subsequently the secretaryship of the Railway

Digitized by Google

Department of the Board of Trade. This latter position he gave up in 1860, but his resignation did not sever his connection with railway work, for in 1866 he served on the Royal Commission on Railways, at which time he gave evidence of strong opposition to the State purchase of the railways of the United Kingdom. Many important questions connected with railway traction have been experimentally investigated by Sir Douglas Galton, notably those connected with the friction of rolling and rapidly moving surfaces, also on the use of automatic brakes.

In 1860, Sir Douglas Galton became Assistant Inspector-General of Fortifications, and, two years later, Assistant Under-Secretary for War, the latter post being held until 1870. From 1870 to 1875, he was Director of Public Works and Buildings under Her Majesty's Board of Works. For 25 years he acted as general secretary to the British Association, an office which he resigned in order to become President of that Association at its Ipswich meeting in 1895. He was elected a Fellow of the Royal Society in 1860, and was also a member of the Institutions of Civil, Mechanical and Electrical Engineers as well as of numerous scientific societies. From Oxford he received the honorary degree of D.C.L., and from Durham and Montreal that of LL.D. In 1865 he was made a C.B., and he became a K.C.B. in 1887.

SAMUEL TROTT.

We regret to record the death, on 11th inst., of Capt. Samuel Trott, at Miami, Florida. His friends will remember that he returned to England at the end of last year so ill that he contemplated giving up command of the "Minia," but he rallied sufficiently to take over charge of his ship. At the beginning of the present year he had, however, to be landed at Halifax and taken to the hospital there, whence he went to Florida. Samuel Trott was born in 1832, and when about 15 years of age went through a full course of navigation and astronomy. At the age of 17 he was apprenticed to the sea for a four-years' term, but long before its expiration he was put in charge of a watch, the captain having recognised the young sailor's sterling qualities. In his 27th year he was placed in command of a sailing ship. The command of a large steamer of an important line speedily followed, and during the next ten years he commanded several of the best mail and passenger steamers of that day. It is, however, in the Atlantic Telegraph cable service that Capt. Trott did that work which most appeals to our readers. In 1874 he had charge of the cable steamer "Faraday," and remained her captain for six years. During that time he laid the Direct and French Companies' cables. In the winter of 1875-6 he crossed the Atlantic three times and made three repairs for the Direct United States Cable Co. In telegraph circles this was looked upon as a remarkable feat, as up to that time it was considered impossible to repair Atlantic cables in the stormy season between the months of October and May. These and other notable achievements in cable work attracted the attention of the late Henry Weaver, of the Anglo-American Company, and in 1880 the services of Capt. Trott were secured for the "Minia," which Capt. Trott commanded for nearly 20 years, and within that period she has made 195 repairs without a single failure, although many of them were in the deepest water of the Atlantic, at depths of 2,530 to 2,597 fathoms. In June, 1897, Capt. Trott broke his own record, having effected a repair on one of the Western Union cables in 11 days, in 2,530 fathoms water, with an expenditure of only 38·6 miles of cable. Capt. Trott was of an inventive turn of mind, and held several valuable patents. These deal not only with ships and shipping appliances, submarine cable-laying and repairing, but also with electric railway work. He was a member of several scientific societies, Fellow of the Royal Metereological Society, and an Associate Member of the Institution of Electrical Engineers.

JULIUS VOGEL.

At Hillersdon, East Molesey, near London, Sir Julius Vogel passed away on Sunday last. The deceased knight was born in London in 1835, and after attending London University School, he became, at the age of 16, a pupil in Dr. Percy's laboratory at the Royal School of Mines, where he studied the chemical arts, especially in their relation to metals. He ultimately went out to Melbourne, and was a leading figure in colonial governmental life for many years. He negotiated with the Eastern Telegraph Co. for the construction and maintenance of a submarine cable between New South Wales and New Zealand, and in the early history of telephony took a considerable interest in the development of telephonic communication and the advancement of the telephone industry.

A. M. RYAN.

Mr. A. M. Ryan, Superintendent of the Eastern and South African Telegraph Co. at Mozambique, died suddenly at that place on the 3rd inst. of fever. Mr. Ryan joined the Eastern Company's service in 1882, and, on account of his electrical knowledge, received early promotion, occupying successively the posts of clerk-in-charge and superintendent on the East Coast of Africa. He was to have left for England by first mail, which only arrived at Mozambique four days after his lamented decease.

M. SECRETAN.

The death of M. Secretan at the age of 63 is announced as having taken place during the past week. M. Secretan will be remembered by electrical engineers chiefly as having been the promoter of the huge copper ring, in 1888, a movement which was set on foot in Paris with a view to corner the entire copper market of the world. The collapse of the ring and the financial disaster which ensued are matters more of general history than of personal biography. Lately M. Secretan was associated with a scheme to amalgamate certain French copper interests with the Elmore companies.

WIRELESS TELEGRAPHY.

The following is an abstract of the discussion that took place at the Institution of Electrical Engineers in connection with Mr. Marconi's Paper on "Wireless Telegraphy":—

Thursday, March 2.

Dr. J. A. FLEMING, in opening the discussion, congratulated Mr. Marconi upon the success he had attained with his system, and thought he had added to their debt of gratitude to him by giving such an exceedingly lucid and interesting Paper. He (Mr. Marconi) was in complete possession of the subject, and everything that he had done was so much in advance of anything that others had attempted that they could only hope to follow after him by asking some questions and endeavouring to obtain a little more information. Therefore he would like to ask one or two questions with regard to the transmitting and receiving instruments. Mr. Marconi had seemed to have abandoned the use of oil. If he remembered rightly, in his first experiments, he had used a Righi transmitter with oil between the poles. He had tried, last summer, a large number of experiments with transmitters of various kinds, and found that oil was practically of no advantage. The real cause of the effect, when a spark was passed between the poles in air, was due to the fact that air possessed a peculiar property of passing, under a given electrical stress, out of a condition in which it was a nearly perfect non-conductor to a perfect conductor, and it did this with extreme suddenness. If they put oil between the poles, although they might be able to raise the two poles to a greater difference of potential before the spark happened, yet, nevertheless, as all oils were carbonaceous substances, after one spark, or perhaps two, had passed, carbon seemed to be deposited between the poles in the form of fine flowing particles, and this prevented the extreme suddenness of the breaking of the dielectric conductor, so that what they gained on one hand they lost on the other. Perhaps Mr. Marconi would tell them whether he had abandoned the use of oil for that reason. Referring to the coherer, he thought he recollected hearing in the early history of the subject, that Mr. Marconi used to exhaust his coherer tube; he did not know whether he did this now. It might be advantageous in making a coherer for long-distance work, but for laboratory and short-distance work there seemed to be no advantage; in fact, it was a greater advantage in many ways to have a coherer which they could easily take to pieces and change the powders, because the sensitiveness of the apparatus appeared to depend very much on getting exactly the right proportion of filings. He quite confirmed Mr. Marconi's remark that the coherer was not the uncertain and treacherous instrument it was generally supposed to be. He found that amalgamating the metal certainly had an advantage that might be due, perhaps, in some way or another to the presence of the mercury vapour. He found that mixing about 5 per cent. of very finely powdered uranium with the nickel filings of the coherer gave a material that was sensitive and certain in its action. By far the most interesting point of Marconi's system was the use of the vertical wire, because he thought they could say with perfect certainty that it was the use of this wire that had enabled him to carry out these long-distance experiments. He had only tried it on a small scale, but he had found the

Digitized by Google

advantage of the vertical wire. Last summer he had experimented with horizontal and vertical wires of the same length, and had got effects over distances with vertical wires that he could not get with horizontal wires. He then asked Mr. Marconi if it were necessary that the earth connection should be complete. When he was at Bournemouth last year witnessing some experiments Mr. Marconi had told him that the earth connection was necessary, and that if this was broken in both places you could not get the transmission over the same distance. It was a most interesting question.

Dr. ERSKINE MURRAY, one of Mr. Marconi's assistants, said that four years ago, when he joined the Wireless Telegraph Co., he was as ignorant of the subject, if not more so, than a good many of those present. Everybody who interested themselves could not help following the experiments from an outsider's point of view, from what they got in the newspapers and technical journals. When he had first gone to Bournemouth and seen the apparatus, he had been much struck by the "ordinariness" of the thing. It was worked just like any other telegraph, not quite so fast as in the General Post Office, but still working at a very rational speed and with very considerable certainty. He thought the increase of the vertical wire with distance was a most interesting feature of the system. Some simple illustration might be taken from the ordinary electrical machine. As they all knew, in a frictional electrical machine the electricity was collected by means of a number of fine points, and the tension on the point was very much greater than on a more rounded part of the conductor. In the case of this vertical wire they had the earth as one large conductor, and these wires standing up on the surface to serve as the fine points of an electrical machine. The surface density increased as it went up, as likewise did the force, but the amount of this increase had not yet been calculated. But probably it would be pretty nearly in proportion to the distance from the earth. The action at the top was more or less proportional as the square of the surface density.

Mr. SYDNEY EVERSHED said he had done some work in connection with wireless telegraphy of the electromagnetic kind, but he had never made an experiment with Hertzian telegraphy. He would like to read the Paper first, and then possibly he might be able to discuss it, or at any rate ask some questions. During the time Mr. Marconi had been carrying out his work, several things had occurred to him which he would like to see cleared up, such as the power used, the law of the variation of distance to which they could signal, the connection between the distance it was possible to signal and the length of the vertical wire and other points of that kind. It appeared, however, that Marconi had anticipated every one of these questions. He (Mr. Evershed) noticed that the law relating to the length of the vertical wire and the distance to be signalled was an exceedingly simple one, and drew the attention of the meeting to the analogy between that and the law he had explained in connection with his own system of wireless telegraphy, a few weeks ago. He had then shown that the distance to which they could signal by means of electromagnetic induction depended, among other things, on the product of the areas of two circuits. During that same discussion Dr. Fleming had referred to the analagous case of the vertical or horizontal wire used in Hertzian telegraphy, and suggested that the true function of that wire was to integrate the electric force over a considerable space and thereby get sufficient energy to work a coherer. That explanation also seemed an exceedingly simple one and was, he thought, the best. It followed from this that Mr. Marconi's law must be true, because the effect of the vertical transmitting wire was proportional to its length, and the effect of the receiving vertical wire proportional to *its* length; consequently, if they doubled the length of the two wires they quadrupled the effect, a law which Mr. Marconi appeared to find fairly accurately fulfilled in his experiments. At any rate, he found it fulfilled with a sufficient accuracy to enable him to design new telegraphs for greater distances. In conclusion, he wished to be the first to congratulate Mr. Marconi on having succeeded in effecting signals between lightships and the shore.

Mr. H. W. SULLIVAN said he would like to ask Mr. Marconi whether his system required a perfect earth—*i.e.*, an earth of little or no resistance. In view of the difficulty which had been experienced in establishing and maintaining an earth connection on outlying and practically non-conducting rocks, such as the Fastnet, through the submerged earth plates being frequently thrown up on the rock in stormy weather by the action of the sea, he thought this was a matter of considerable importance. If Mr. Marconi had successfully solved the difficulty, as seemed to be the case, of communicating in all weathers with outlying lighthouses and lightships, he had conferred a great and lasting benefit on the world.

Mr. W. P. GRANVILLE asked if the vertical wire in this system was measured from the sea line, or from the height on which it stood. For instance, the standard on which the wire was erected at Alum Bay was on a hill, perhaps 100ft. or 200ft. in height, and the same at Bournemouth, and he should like to know whether the height of the top of the vertical wire above the sea plane made any material difference. Another question he asked was with regard to neighbourhood of conducting masses at the transmitting or receiving end. In the case with which he had been more immediately interested in, viz., the Fastnet rock, the whole mass of the tower was of thick boiler plate, as were all the buildings on the rock. Had Mr. Marconi, under such conditions as these, found any great difficulties?

Capt. BRETT thought it somewhat difficult to discuss a Paper which was mainly a series of facts that had taken place. However, there seemed to be a good deal of interest in the question of the earth connection, but not wishing to anticipate Mr. Marconi in his reply, he would only say that, during some experiments Marconi had, at his request, suddenly disconnected the earth connection of the receiver but the signals came just as before, the receiver being on shore, so that it would appear that, under these conditions, the earth connection was not a necessity for the working of the apparatus, at any rate up to 12 miles. He was prepared to accept that the earth connection to the transmitter was a necessity, because it afforded an oscillating character to the discharge, but in the matter of the receiver the question of a bad or good earth did not come into the question; no earth at all was sufficient. Personally he would like to ask Mr. Marconi if he had continued these experiments to any great extent over greater distances.

Capt. VIVIAN confirmed everything that had been said about the success of the Marconi system in connection with lightships, and mentioned that experiments had been in progress for over two months on the Kentish coast.

Capt. KENNEDY, R.E., had taken part in many of Marconi's experiments, especially those on Salisbury Plain and in the Isle of Wight, and he had also read a Paper before the Royal United Service Institution dealing chiefly with the military application of wireless telegraphy. As regards the question of fixed stations, such as forts and camps, he thought the difficulties had been solved, but when they came to an army in the field it was another matter. They could not carry 100ft. poles about with them. They had to find some other way of raising the vertical wire, as it was evident they could not do without it. He had tried several experiments with kites and balloons, and one of the advantages of these was that they got rid of all the difficulties of insulation. They were practically unlimited in the length of their wire; it was as easy to have a 1,000ft. wire as it was a 10ft. wire. In one experiment at Bath he had put up two miles of wire on one kite, although it was needless to say that the enormous impedence on this wire was too much. He thought he was right in saying that about a year ago he was the only true believer in Mr Marconi and his system, excepting, of course, Capt. Brett and Capt. Jackson, of the Royal Navy, who both had been staunch supporters.

Prof. J. PERRY (in the chair) asked Mr. Marconi if it was necessary to have any earth connection. It was one of the most difficult things for him to understand why there should be any earth connection necessary.

Thursday, March 9.

Mr. JOHN GAVEY congratulated Mr. Marconi on the advance he had made in perfecting this system during the past 15 months. He had been associated with him in his early experiments, and had taken an active share in those carried out across the Bristol Channel. These experiments were to some extent crude, in the respect that the apparatus was practically untried and uncertain in its action. They had, however, succeeded in obtaining thoroughly good signals from one side of the Channel to the other, and had learned enough then to render it desirable to proceed with further experiments. It was arranged by the Post Office for these further experiments to be made, and the necessary apparatus was immediately put in hand. Some months elapsed before it was ready for use, and a further series of experiments were undertaken by the Post Office in the neighbourhood of Dover. The objects in view were to ascertain the law connecting the height of the conductors with the distance over which transmission was possible, and generally to test the system. They obtained the permission of the War Office to provide a transmitting station at Fort Burgoyne, near Dover, and a number of receiving stations were put up at different distances. The results of these experiments led them to certain conclusions, most of which had been verified by Mr. Marconi since, and many of them repeated in his Paper. These proved the law of the square of the height of the wires, but they went a little further. They found that with single elevated conductors, syntony did not come into the effect at all, so that not only did distances to which it was possible to transmit increase as the square of the height, but within certain limits it increased as the product of two vertical conductors of irregular height. Assuming that it were possible to transmit signals over certain distances with two conductors 50ft. high—the square of which would be 2,500—they could, under favourable conditions, transmit over the same distance with two conductors of different heights, which would give the same product. They found further, that there were marked effects on the syntony if a capacity were placed at the top of the vertical conductor, and, further still, they found that the use of a capacity enabled them to traverse or transmit over a certain distance with a lesser height of conductor. Another curious phenomenon they came across was that they required a greater height of vertical conductor to transmit signals over land below the sea level. Taking the experiments in the Bristol Channel as a guide, and also the subsequent experiments made by Mr. Marconi at Spezzia, they had calculated that it would require a vertical conductor 35ft. in height to transmit signals over a mile of water, but, to their surprise, they found it required a vertical conductor 50ft. high to do this. They naturally made numerous experiments to ascertain the cause of this apparently abnormal result, and ultimately they asked Mr. Marconi to come down with some of his own most recent apparatus, and they found that there *was* a distinct difference in the power required for transmitting over land as compared with that required over water. Subsequently he observed that Prof. Slaby, of Charlottenburg, who had been sent over by the German Emperor to watch the experiments in the Bristol Channel, had obtained the same results in his experiments conducted in Germany. He (Prof. Slaby) had attributed the difference in the results over land and water to the particles of dust floating about in the atmosphere, but with due deference to such a high authority as Prof. Slaby, he was afraid he could not agree with this view, because, in the case of Dover, there would scarcely be such a wide difference in the atmosphere over the grounds immediately adjoining the Straits and over the Straits themselves. He ventured to suggest that it was rather due to the reflection from the surface of the water, for water over such a distance as one mile they could assume to be an almost even plane reflecting mirror. There was no doubt that as these experiments over water were generally conducted from considerable heights, many of the waves, which would otherwise be reflected into space, were reflected back from the water and impinged on the receiving vertical wire, whereas, probably on land, many of these waves would be absorbed or possibly reflected right away into space. With regard to the height of the vertical wire, he noticed that Mr. Marconi had made a very considerable reduction in this, having now brought it down to 20ft.; but he would like to know whether this was a practical

Digitized by Google

working height with a fair margin of safety, which would admit of working under all conditions, or whether this was the shortest height which could be obtained with skilled operators at the transmitting and receiving instruments. He had come across another interesting thing in connection with the Post Office experiments. When they discovered the discrepancy that existed between the results over water and over land, they investigated every possible cause which might have led to this difference. Naturally enough they immediately suspected the earth, for, as everyone knew, on the chalky downs in the neighbourhood of Dover, it was very difficult to get a thoroughly good earth at a moderate depth. They therefore disconnected the earth entirely from the coherer, and substituted an ordinary coil of wire, one end of which was insulated; in fact, they substituted a capacity for an earth. They found the signals were equally good when the capacity was substituted for the earth, and they have gradually reduced that capacity from a length of about 200 yards to a simple strip of brass about 2ft. long, and with this very small capacity they could still receive just as well as they did when the coherer was connected to earth. They tried the same effect at the transmitting end, but found they could not get good signals without an earth connection. Probably, if they had used a capacity of sufficient size to dispose of the large amount of energy sent into the transmitting vertical wire, they could have done without an earth at either end. They also found that the oil of the transmitter in the Righi form was quite superfluous. A simple air gap in the coil was all that was necessary. With reference to the question raised as to the amount of energy taken in producing these results, he thought it was rather a question of frequency than power, and this was shown by experiment. They had a very large coil capable of giving a 20in. spark, but as a general rule they adjusted it so that with 5 amperes it would give 6in. sparks. As a matter of fact, when they increased the current to 10 amperes to get a 20in. spark, they had to screw up the contact breaker very tightly, which reduced the periodicity, and they got a worse result with 10 amperes and slow vibration than with 5 amperes and rapid vibration. They also had tried large copper reflectors of the type exhibited by Mr. Marconi, and at first he thought they were going to get some very promising results, for at a distance of half a mile, with the transmitter in the focus of one of the reflectors, they could pick up the signals in the open air; but when they extended the experiment they got very disappointing results, and after a time they abandoned the idea. It appeared that even slight undulations that did not come in the direct line of the reflectors, were quite sufficient to prevent the satisfactory transmission of signals. He gathered from Mr. Marconi's Paper that he had obtained satisfactory signals up to two miles by means of reflectors; it appeared to him that signalling by means of reflectors would be far and away more satisfactory than signalling from vertical conductors. If they signalled from vertical conductors and from a large number of stations within a limited range, whatever was sent on one conductor could be heard on all the others, and it was only possible to transmit one message at a time. The use of reflectors would remedy this evil, and would be a great advantage in the practical application of the system. In a Paper like this he thought it was always a difficult matter to know when to draw the line between popular description and technical results; but, perhaps, in his reply, Mr. Marconi would refer to one or two matters of practical importance. First of all, the question of screening the receiving apparatus from the effect of the violent surgings in the transmitting apparatus was one of very great interest. The difficulty had been solved by Capt. Jackson in one way, Mr. Marconi had solved it in another; but if he (Mr. Marconi) saw his way to giving, in his reply, some explanation, it would be of great interest. Other points would also probably strike the author, such as the protection of installations from the effects of lightning. The vertical wire used was practically a lightning conductor, and to introduce a lightning conductor of this sort into the centre of a building or lightship without adequate protection would be very undesirable.

Mr. MERVYN O'GORMAN thought it possible to explain telegraphy without wires over long distances without assuming Hertz waves at all. A coherer was not only a detector of Hertz waves, it was really a detector of minute constant differences of potential. He suggested that there was a minute difference of potential, which any other instrument would not detect, set up through the *earth* and not through the air space between the two stations.

Mr. E. TREMLETT CARTER said it would be interesting to know how Mr. O'Gorman explained the action of reflectors on his theory.

Mr. O'GORMAN said he did not suggest that the coherer did not work with reflectors, he had merely advanced a hypothesis of an alternative method of wireless telegraphy.

Mr. W. P. GRANVILLE said that 100 Obach cells had been mentioned in the Paper as the power at Alum Bay, but if his memory did not fail him, he thought he had heard that these 100 Obach cells were not used directly connected to the induction coil, but were used to charge an accumulator off which the induction coil was worked. He would like to know if this were correct, because, if it was, it showed that they could not use the system in places where they were not able to have a dynamo. With regard to the screening effect, they had heard from public accounts that even three men-of-war interposed between the receiving ship and the signalling station have not prevented the receipt of messages, while they heard again that the waves are reflected. The two things did not agree. Which was correct?

Mr. L. MILLER asked if it would not be better to use several spark gaps, in series, for the transmitter, as it appeared that when using horizontal wires two gaps were certainly better than one, and more, he thought, would be of still greater advantage. He should also like to know which were the most sensitive metals to use for the coherer, apart from the question of de-cohering. He had had an opportunity of working with an extremely sensitive relay that worked with less than $\frac{1}{15}$th milliampere, but to his surprise he did not get any better results than with a less sensitive one. It seemed to him that a coherer was wanted that would break down if a succession of weak waves reached it. He had heard of carbon coherers acting in that way, and would be glad to know if anyone had made experiments with a carbon coherer.

Mr. A. A. C. SWINTON, replying to Mr. Miller's inquiry as to carbon coherers, said that he made experiments some time ago to see if Röntgen rays would affect the resistance of carbon, and apparently it did so, but he had found out afterwards that it was due to the contact-breaker of the induction coil.

Mr. A. C. BROWN had found that carbon coherers did break down gradually. One wave would slightly reduce its resistance, another would reduce it more, and so on.

Prof. SILVANUS P. THOMPSON (in the chair), speaking on the advantage of having the vertical conductors earthed at the bottom, said it seemed to him that there was one advantage that had never been pointed out yet, viz., that the earth directly below the vertical conductor played the part of a mirror. In a great many problems it was possible with advantage, to introduce optical ideas. Some years ago, in conjunction with Mr. Myles Walker, he had pointed out that many electromagnetic problems might be solved by the application of the idea of masses of iron acting as a magnetic mirror. Suppose they had a solenoid, say 2in. in diameter, and 6in. long with a certain number of coils of wire traversed by a current; the coil would have a certain magnetic moment. If they put against the end of that solenoid a large sheet of iron sufficiently thick and of sufficiently high permeability it would practically act as a mirror, so that the coil with the sheet of iron behind it would have exactly double its previous magnetic moment. In the Marconi transmitter the earth connection caused the earth to act as a mirror, and doubled the virtual length of the vertical rod. On the question of the variation of distance over which they could signal on land or water, he thought here, again, optical ideas could very well be introduced. He thought it possible to account for the greater absorption of the waves over land, as compared with water, by assuming that the conductivity of the earth was greater than that of water. It might seem curious to say so, but it appeared to be something of the sort. With regard to coherers, he said it was no use putting a mirror within a quarter of a wave length of the thing that was giving out light. Hertz had pointed this out. If they referred back to Hertz's researches, they would find that he used mirrors something like 10ft. high, and the oscillator was about 8in. long.

A hearty vote of thanks was accorded Mr. Marconi at the conclusion of the discussion.

DR. WEHNELT'S ELECTROLYTIC CURRENT INTERRUPTER.

At the meeting of the Institution of Electrical Engineers, held on March 9, Mr. A. A. Campbell Swinton exhibited Dr. Wehnelt's new electrolytic current interrupter. It was Dr. Fleming, he said, who, in the discussion on Dr. Lodge's Paper, gave the reason why there was great difficulty in obtaining syntonic results with Hertzian wireless telegraphy as opposed to magnetic wireless telegraphy, with which Dr. Lodge's Paper dealt. The real reason was because there is at present, or had been until recently, no means of obtaining continuous trains of Hertzian waves. Some years ago he made some experiments on this subject, and he showed curves at the meeting of the results obtained then by analysing the spark in the primary of a Tesla coil by means of a revolving mirror; and, as they saw, he got about five oscillations. This number was the maximum obtainable, and the whole series took place in about $\frac{1}{50000}$th of a second. The next lot of oscillations occurred in the opposite direction because he was working with alternate currents of 100 periods per second. Quite recently, a new form of contact breaker had been invented by Prof. Wehnelt, of Charlottenburg, which had an advantage in that it made it possible to get discharges from an induction coil, not as with ordinary contact breakers, say 30 or 40 per second, but 1,000 or more, and under certain conditions still more could be obtained. The apparatus consists of a vessel containing dilute sulphuric acid—about 1 part of acid to 5 of water—in this is dipped a large lead plate and also a glass tube to the end of which is fitted a platinum wire. The inside of the tube may be filled with mercury, or a larger wire could be used. They must not take the platinum wire to the top of the vessel because it would get hot. This formed the whole of the contact breaker. An ordinary induction coil without the contact arrangements was connected straight on to the 100-volt mains through this apparatus, and the only thing to be careful about was to see that the platinum wire electrode was positive. The apparatus would not work if the lead plate was positive. The exact action seemed fairly simple at first sight, but on going into it further it became more complicated. Obviously, oxygen was given off at the platinum pole, and one could imagine that a large amount of oxygen was given off round the pole, thus making an insulating sheet, and thereby the current would be interrupted. The oxygen was then absorbed by the solution, and the current started again. This seemed very simple, and one reason, possibly, why it took place when the platinum wire was positive, and not when it was negative, was that oxygen was more soluble in water than hydrogen. As a matter of fact, this explanation did not cover the facts, and he did not know the true explanation himself. There was a great deal of heat developed; indeed, there was an arc formed at the end of the platinum wire. This contact-breaker, moreover, would

Digitized by Google

not work upon a non-inductive circuit; it would not work if, instead of having the primary of an induction coil or magnet, they had a lamp resistance in series with it. In explaining the working of the apparatus he said that, as he removed the core of the magnet, the note changed, the periodicity of the discharge depending on the amount of the magnetic inertia of the circuit. As he reduced the magnetic inertia, or self-induction of the circuit, the note went up. He thought it was, undoubtedly, important from the point of view of wireless telegraphy, and very likely in other ways, because it seemed to be the first real advance made for many years in continuous interruptions at very high frequencies.

Mr. E. TREMLETT CARTER asked if the effect observed with this interrupter would in any way suggest that it acted as a Trevelyan rocker—*i.e.*, whether it was a thermal effect. If the condensation of steam would allow contact to be made again, or, if the alterations between heating and cooling caused by the passage of the current produced this effect, he thought they would get a vibration very much like that of the Trevelyan rocker.

Mr. SWINTON said that, of course, temperature had a good deal to do with it. Steam very likely had very much the same effect in this case as the gas, due to electrolytic decomposition, but neither one or the other could account for the fact that the apparatus would not work upon a non-inductive circuit, and that when it was upon an inductive circuit, the induction in the circuit determined the frequency to some extent.

Prof. SILVANUS P. THOMPSON said there was clearly something in the nature of resonance taking place. It had long been common knowledge that the deposit of gas upon an electrode had the effect of making that electrode act, to a certain extent, as a capacity. In the researches of the late C. Varley they found this fact stated, and again in a Paper published in the *Journal* of the Russian-Physico-Chemical Society, by Prof. Sloughinoff, in 1881, upon the intermittence of the discharge at a small electrode when a sufficiently high E.M.F. is applied. Prof. Sloughinoff had examined it in a rotating mirror, and found that it was intermittent.

THE INDUCTION MOTOR.*

BY ERNEST WILSON.

Introduction.

The advent of the induction motor may be said to have marked an epoch in the use of alternate currents for power distribution, for, up to the time of its introduction, the only alternate current motor for comparatively large sizes was of the synchronising type. This type of motor, as is well known, requires to be run up to such speed that the frequency of the armature corresponds to the frequency of supply before being switched on to the circuit. For small sizes the ordinary direct current motor with laminated magnets can be, and was, employed, but the want was felt of a motor possessing the characteristic features of the direct current type, and capable of dealing with considerable power. The transmission of energy by the aid of electricity for the propulsion of tramcars and electrical locomotives may be cited as an example in which, one may say, until quite recently, the direct current motor has been exclusively used. In this case a motor is required which is capable of exerting an initially great torque for starting purposes, it must be easily controlled by drivers, and must be efficient. Consider the case in which power is transmitted from a distant waterfall to a district in which electrical traction is required. We should probably find that the turbines are coupled to two- or three-phase alternate-current generators, which supply directly or through step-up transformers to the line wires. At the receiving end the energy is delivered to a motor generator directly, or through step-down transformers, such motor generator converting this energy into the form of direct current for transmission to the cars by any of the well-known systems. This motor generator is of the synchronising type, and should be run up to synchronising speed before being switched on to the supply circuit. Now, if alternate currents could be employed on the car itself, it follows that no running machinery would be required in the substation, since the requisite reduction of potential difference could be accomplished by static transformers. At the present time the three-phase induction motor is being used at Lugano on the street cars, and is about to be installed on other lines, so that it is actually employed in practice. Now for two or three-phase currents to be transmitted to the car, it requires three conductors; if the rail be employed as one, then two other insulated conductors are required—these are overhead at Lugano. According to usual construction, the motor, even if single-phase, requires two or three-phase currents to start properly; that is, to give an initial torque of the required magnitude. The subject, therefore, has great practical importance at the present time. The primary object of this Paper is to investigate in an actual motor the conditions upon which the starting torque depends.

The Motor.

The motor experimented upon was kindly lent by Mr. Alexander Siemens to the Siemens Laboratory, King's College, London. Fig. 1 is a side elevation, and Fig. 2 an end view of the motor which is intended to deliver 15 B.H.P. when running at 1,000 revolutions per minute, and supplied with a single-phase alternate current at 220 volts, the frequency being 50 periods per second.

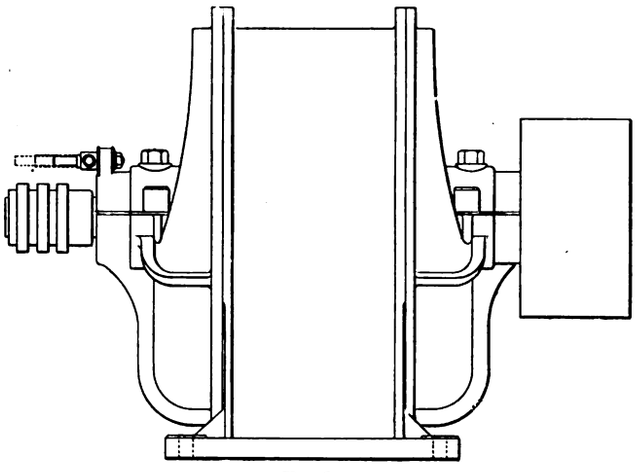

Fig. 1.

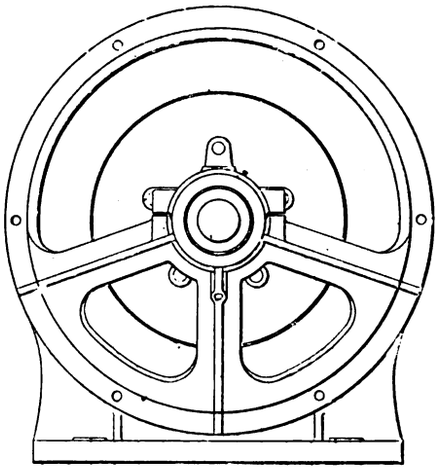

Fig. 2

In order to measure the initial torque, a beam having a radius of 3·5ft. is fixed to the shaft, and the pull in pounds measured at this radius by a spring balance, the armature being brought to its zero position by raising the spring balance by aid of a rope passing over a pulley. The actual observations of pull are, at the best, rough, since the readings, when small, are seriously affected by the friction of brushes and bearings, but they are sufficiently accurate for the purpose of this Paper. Before dealing with the actual experiments it will be well to describe the motor. Its stationary portion, Fig. 6, is wound with two circuits, marked respectively A and B. These circuits are so distributed that two-phase currents are required to give an approximate rotating magnetic field for starting purposes, and, when once started, the motor is intended to work on the single phase. The conductors are placed in slots, the main winding B consisting of 156 bars, and having a resistance of 0·038 ohm. The auxiliary winding A has 144 bars, and resistance 0·045 ohm. The armature (Fig. 6) is wound three-phase with three circuits, which are pooled together at one end, and connected respectively to three rings insulated on the shaft. These rings are connected through brushes to a non-inductive rheostat capable of varying the resist-

ance externally inserted in each circuit by steps, as follows :—Open circuit, 2·37, 1·03, 0·42, 0·13 ohms at about 15°C., and short circuit; the ends of these three external resistances in the rheostat remote from the brushes are pooled together. Each armature circuit has 48 bars, and a resistance of 0·025 ohm, the bars being placed in slots in the armature. There are 150 slots in the stationary portion and 72 slots in the armature, two bars being placed in each slot, and the number of periods per revolution is three. The radius of the armature is 22·2cm., and the length of core parallel to the shaft 17·8cm.

The coils A B were supplied with currents from two Siemens alternators* separately, or, if required together, in any desired

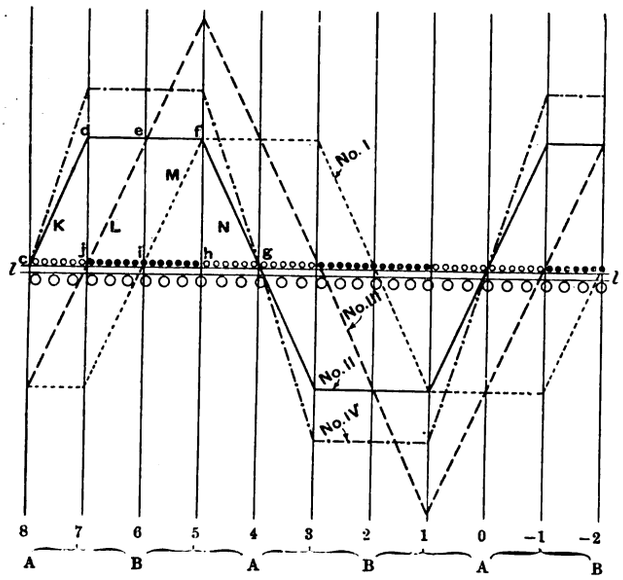

FIG. 3.

phase. By aid of a Kelvin quadrant electrometer and revolving contact maker fixed to the shaft of the alternators, the currents in the respective circuits have been deduced from observations, at different positions of the phase, of the potential difference between the ends of a non-inductive resistance in the circuit. The potential differences across the circuit were reduced when necessary to suit the sensibility of the electrometer by aid of considerable non-inductive resistances forming a shunting ratio.

SYMBOLS.

In the Paper the following symbols are used :—E_1, E_2, are the volts across the circuits A and B respectively; I_1, I_2, are the total inductions per turn in C.G.S. units in the circuits A and B; m_1, m_2, are turns in circuits A and B ($m_1=72$, $m_2=78$); x_1, x_2, currents in amperes in circuits A and B; R_1, R_2, resistances of circuits A and B ($R_1=0{\cdot}045$ ohm, $R_2=0\ 038$ ohm); T periodic time

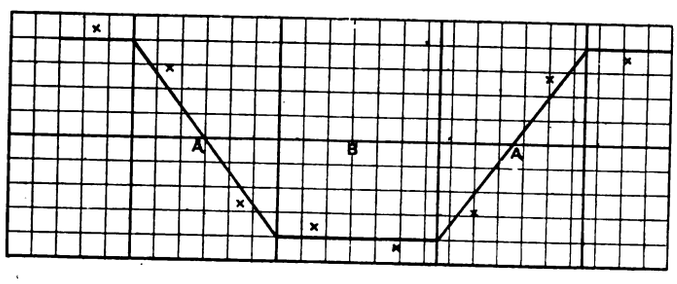

FIG. 4.

in seconds; f frequency of supply in complete periods per second; N number of poles per circuit per revolution = 6; m number of coils per period on stationary portion; θ one period of surface revolution; l length of armature and stationary iron cores measured parallel to axis = 17·8 cm.; r radius of armature = 22·2 cm.; l_1 length of air space measured radially = about 0·175 cm.; A_1 area of air space over one group of windings, B, in square cm.; l_2 length in cm. of teeth on armature and stationary portion of motor; A_2 area of teeth in square cm.; l_3 mean length of induction in iron in cm.; A_3 area of iron in square cm.; I total induction by characteristic curve; ν leakage coefficient; B induction in C.G.S. units per square cm.; $r_1=r_2=r_3$ = resistance of each armature circuit = 0·025 ohm; $\rho_1=\rho_2=\rho_3$ = extra non-inductive resistance in each armature circuit; these can have values ∞, 2·37, 1·03, 0 42, 0·13 and 0 ohms; $n_1=n_2=n_3$ = conductor turns on each armature circuit = 24; $y_1\ y_2\ y_3$ currents in the armature circuits respectively, in amperes; $e_1\ e_2\ e_3$ electromotive forces of the respective armature circuits C, D, E, in Fig. 6—that is, they are the potential differences between the ends of the respective circuits corrected for current into resistance 0 025 ohm.

THE MAGNETIC CIRCUIT.

Let the horizontal lines 11 (Fig. 3) represent the surfaces of the armature and the bored face of the stationary portion straightened out. The ordinates represent induction density, the areas induction. The windings A, B, are diagrammatically represented ° ° ° ° ° and • • • • • respectively. The lower row of large circles represent the armature conductors. Consider the winding A, and suppose that it only is the magnetising coil. One would expect the distribution of induction over the bored face to take the form represented by the full line (Curve No. II.), assuming for the moment that there is no leakage. Let the area $c\,d\,j$ be called K; $j\,d\,e\,i$, L; $i\,e\,f\,h$, M; and $h\,f\,g$, N. Then K + L + M + N is the total induction over

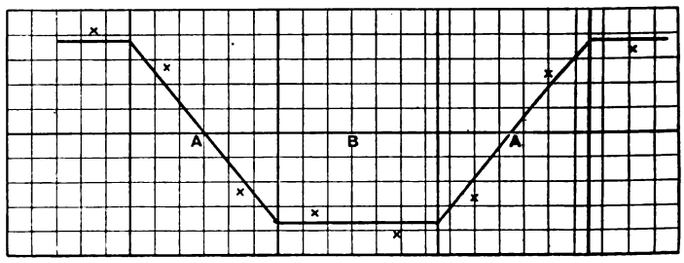

FIG. 5.

the half period ($\theta/2$) between c and g. If the characteristic curve for the surface $j\,h$ be worked out in the ordinary way, the total induction I given by it will be represented by the areas L + M.

For the purpose of finding the distribution of induction near the bored face, a series of insulated copper wires numbered 1, 2, 3, 4, 5, 6, were stretched across the surface parallel with the axis of the machine, and placed relatively to the coils A and B, as shown in Fig. 3; the wires have a diameter of 0·2mm., and touch the surface of the bored face. Electromotive forces have been observed between adjacent wires for different positions of the phase by aid of a quadrant electrometer and revolving contact maker attached to the axle of the alternate current generators; first when

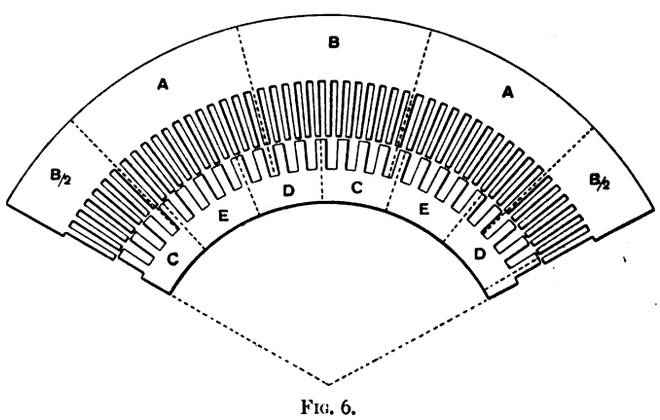

FIG. 6.

the motor was supplied with one-phase, second when supplied with two-phase currents. These E.M.F. curves have been integrated, and give therefore at any epoch the average total induction over the area between the two wires considered. These wires cannot give the distribution of induction *in* the stationary portion itself, but a good deal can be inferred from the curves obtained. Deal with the single phase curves first. The coil A was chosen for the single phase current. Table I. gives particulars of the test in which the frequency was 51·7 and the square root of mean square value of E_1 63 volts. We see that the curves dI_1/dt and (2 - 3), (3 - 4), (4 - 5), (5 - 6) are in phase. Their areas have been taken, and give total maximum inductions of 0·37, 0 1097, 0 0723, 0·0679, 0·0891

* For description of these machines and revolving contact maker, see *Phil. Trans. Roy. Society*, Vol. CLXXXVII. (1896), A. pp. 229-252.

in 10^6 C.G.S. units. The average inductions given by the exploring coils have been plotted in Fig. 4, in which the abscissæ are as in Fig. 3, the surfaces of the armature and bored face of the stationary portion of the motor straightened out. The full line in Fig. 4 has been drawn, and encloses an area per half period equal to 0·1097 + 0·0723 + 0·0679 + 0·0891, that is, equal to the sum of the inductions given by the exploring coils shown in Fig. 3. Another set of curves at higher maximum induction density (Table II.) give 0·676, 0·211, 0·135, 0·122, 0·168 in 10^6 C.G.S. units. These points have been plotted, and the full line drawn through them as shown in Fig. 5, enclosing the area represented by 0·676 + 0·211 + 0·135 + 0·122. The frequency in this case is 56 and $\sqrt{\text{mean}^2}$ E_1 118 volts. The object of drawing the curves in Figs. 4 and 5 is to show that there is ground for assuming the form given in curves Nos. I. and II., Fig. 3. Assuming, then, in Fig. 3 that L=M=K+N, and that K=N, one would expect the magnetising coil to experience a reaction represented by the rate of change of the average of areas L+M and L+M+K+N; *i e*, 1·25 (L+M). Further, the exploring coils (2-3), (3-4), (4-5), (5-6), if the air space experienced the whole induction, would give over half a period ($\theta/2$), $1\frac{1}{2}$ (L+M). In any case, on the assumption of distribution of induction represented by the full line, the maximum value of $\int\frac{dI_1}{dt}dt = 1·25/1·5 = 0·83$ of actual total induction. If the distribution were represented by a sine curve, this coefficient would be 0·85, and has been obtained graphically. Referring to the figures 0·37/0·83 = 0·446, and 0·676/0·83 = 0·814 in 10^6 C.G.S. units. Of these it appears that 0·339 and 0·635, in 10^6 C.G.S. units, gets into the air space—that is, the leakage is 24 and 22 per cent. respectively. The fact is, there is serious leakage across the teeth in this machine; but the coils 1, 2, 3, &c., have a thickness of 0·2mm., and are covered with one layer of silk, so that they account for a portion of the air space. Coming now to the characteristic curve. In Fig. 6 the length of the air space (l_1) measured radially lies between 0·15cm. and 0·2cm.; the area of the air space A_1 is taken to be 210 sq. cm.; l_2 is taken to be 15·2cm., and is the length of the teeth on armature and stationary portion; A_2, the area of the teeth, is taken to be 105 sq. cm.; l_3 is taken to be 48cm., and is the mean length in the iron; A_3, the area of the iron, is taken to be 415 sq. cm. Then the equation to the characteristic curve is

$$\frac{4\pi m_1 x_1}{10\times 3} = 2\left\{\frac{l_1 I}{A_1} + l_2\frac{I}{\mu_2 A_2} + l_3\frac{Iv}{\mu_3 A_3}\right\}$$

where $m_1=72$ and is the number of conductor turns; x_1 is the current in amperes; I is the total induction over area A_1, that is area *jh* (Fig. 3) of the armature, *v* is the leakage co-efficient which is taken to be 1·5. No great refinement can possibly be attempted in the results of characteristic curve calculations, since the air space length l_1 is not known very accurately and is of such importance. Taking an ordinary induction curve for transformer plate, and $l_1=0·175$cm., the characteristic curve for $x_1=14·4$ would give I the value $0·215\times 10^6$; for $x_1=25$, I would have the value $0·390\times 10^6$. We note that the maximum inductions given by coils (2-3)+(5-6) are 0·200 and 0·380 in 10^6 C.G.S. units respectively. This is sufficient to show that if the air space length were known accurately, the result might be predicted with sufficient accuracy for practical purposes.

(To be continued.)

CORRESPONDENCE.

THE WEHNELT INTERRUPTER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In working in the laboratory of the Technical College, Finsbury, upon the phenomena of the liquid interrupter recently applied by Wehnelt to the induction coil, several facts have been observed which throw light on the causes of this interesting matter. The actual experiments have been entirely in the hands of my assistant, Mr. J. Dennis Coales, and of Mr. W. Royal Dawson, senior student in the department.

The phenomenon is essentially one of resonance, and depends upon (1) the presence of self-induction in the circuit, (2) the operation of the small platinum anode in the acid as a capacity. The flow of current from this anode when a continous voltage is applied is unstable, since the evolution of gas on its limited surface checks the flow until the accumulating gas is bodily removed from the surface. Given this initial instability, given the well-known fact that a polarisable platinum anode has a capacity, and given that self-induction is present, there at once follows by electric resonance an oscillatory current superposed upon the continuous current; the period of the oscillations depending, as is well known, on the product of the self-induction and the capacity.

As was observed so far back as 1881 by Slouginoff (*vide* the *Journal* of the Russian Physical and Chemical Society, Vol. 12, p. 192; or *Beiblätter*, Vol. 5, p. 901) the discharge is intermittent. This may be seen by examining, in a revolving mirror, the luminous point which appears at the anode. This experiment was shown by Mr. Coales in the library of the Royal Institution last Friday. The frequency of the discharge can be varied, both by varying the size of the anode, and by altering the self-induction by introducing into the circuit a choking-coil with a movable core. We have also observed several curious results by inserting two or more liquid interrupters in series or in parallel. Two in series act in general as a single one of about half the capacity. We have found that the regularity of the intermittences is improved by the device of causing a jet of acid to flow rapidly past the anode so as to aid in the regular removal of the bubbles of oxygen.

If the pressure on the surface of the liquid is raised, the current passing through the break increases: as an instance when the pressure was raised from 1 atmosphere to 3 atmospheres the current changed from about 5 amperes to about 6 amperes, the frequency of the break on the other hand decreasing.

By use of incandescent lamps and of voltmeters we have further verified the resonant effects. The following experiment is quite easy, and at once suggests many variants, by its exact analogy with similar experiments made with alternating currents. A choking-coil was joined in series with a liquid interrupter—a platinum wire tip projecting into a beaker of acid with a sheet of lead as kathode—and the two were together placed across the mains of our electric lighting circuit, which is a continuous current supply at about 100 volts. Under these circumstances, though the voltage at the terminals was only 100 volts, a 150-volt lamp in parallel with the choking-coil was well illuminated. In another experiment, with varying self-induction, the voltage across the terminals of the choking-coil was 91 volts when a 3-ampere current passed; but, on increasing the self-induction, the current dropped to 2·6 apparent amperes, and the voltage rose to 159 volts, though the terminals of the circuit were only at 100 volts. If, with a suitable voltmeter, the voltages across the liquid interrupter and across the choking-coil are separately measured, their values added together always exceed that of the voltage of the mains which supply them; and, with a suitable adjustment of the parts, they may each separately be greater than the original voltage.—Yours, &c.,

SILVANUS P. THOMPSON

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Dr. Wehnelt's high-speed electrolytic break, which was exhibited in action at the last meeting of the Institution of Electrical Engineers by Mr. Swinton, is undoubtedly an addition to the resources of the physical laboratory. After hearing Mr. Swinton's explanations, I tried the break with an 8in. Apps induction coil, and obtained the flaring arc-like discharge between the terminals of the coil. This discharge, as Sir William Crookes pointed out some time ago, is really the flame of burning nitrogen. If an adjustable non-inductive resistance is placed in series with the electrolytic break and with the necessary inductive resistance or choking coil, it is possible to vary the number of discharges of the coil per second from one or two per second up to a thousand or more. It is best to use a choking coil of high inductance and very low resistance, and add the required resistance to the circuit by non-inductive resistances in series with the choking coil. If a couple of large Leyden jars are connected in the usual way across the secondary terminals of the coil, the discharge is quite startling when the coil is worked with the high-speed break.

If, in addition to the Leyden jars, a Tesla coil is employed as usual to take up the oscillatory discharge of the jars, the secondary high-frequency discharge is much increased. The electromotive force in the secondary circuit of the Tesla coil is also greatly exalted. It is well to proceed cautiously in trying this experiment. I have broken down the insulation of my Tesla coil in a dozen places this afternoon in trying the effect. If the electrolytic high-speed break is used with a Tesla coil it is necessary to have a secondary circuit very well insulated with a dielectric of considerable strength. The break will be especially useful in spectroscopic work, as the discharge with a Leyden jar in circuit with the coil secondary is exceedingly brilliant and continuous. The positive electrode of the break is best made by passing a stout copper wire down a narrow porcelain tube, the copper wire having a platinum tip welded to it. The platinum tip should just protrude through an ebonite plug which stops up the bottom of the porcelain tube. If the platinum wire is sealed into a glass tube it gives endless trouble by continually cracking out.—Yours, &c., J. A. FLEMING.

London, March 15.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At a time when Wehnelt's interrupter is attracting a good deal of attention it may be of some little interest to point out a use to which it may be put, apart from that of working induction coils.

There can be little doubt, I think, that electrical resonance effects play an important part in the working of the interrupter which seems to act largely as a sustainer of electrical oscillations in its own circuit, for which it performs the same kind of function as the reed does for the organ-pipe. As evidence in support of this view may be mentioned the very noticeable influence which the presence of self-induction exercises on the intensity and pitch of the note given by the interrupter as well as on the light effects produced at the anode. Keeping the current constant, the introduction of a large self-induction lowers enormously the pitch of the note, making it, at the same time, much louder, while the withdrawal of self-induction raises the pitch. With only a very small self-induction the interrupter works less satisfactorily, and, indeed, the existence of a certain amount of self-induction seems to be, in a great measure, essential to its proper action. The capacity of the anode acting like a condenser supplies, of course, the other element necessary for the production of resonance. One result of the existence of oscillatory currents would be the production, by electrolysis, of a mixture of oxygen and hydrogen at the anode, giving rise, in turn, to a succession of minute explosions and correspondingly sudden interruptions of the current. A close inspection of the anode, while the interrupter is at work, lends colour to this view of the nature of the actions which take place there.

That the interrupter is capable of exciting and maintaining oscillations in a circuit containing capacity and self-induction can be shown very easily by connecting a condenser across the terminals of the interrupter. A considerable current, easily measurable on an ordinary electro-dynamometer, will then flow into the condenser, and from the magnitude of this current and the value of the electromotive force between the condenser terminals, we can, assuming the condenser current as simple periodic, deduce the frequency of the alternations. Now, my experiments show that the frequency so determined is, within very wide limits, altogether independent of the pitch of the note which the interrupter happens to be emitting, but depends solely on the capacity of the condenser and the self-induction of any coils which are included in the circuit. With the condensers I have been using, having capacities varying from 0·33 to 1·33 microfarads, I have obtained frequencies ranging from one to three or four thousand alternations per second; and, no doubt, still higher frequencies could be obtained with smaller capacities. The condenser current is steady enough to measure with accuracy. By placing a coil in series with the condenser and dynamometer, and measuring the electromotive force between its ends and also between the condenser terminals, it is possible from the dynamometer and voltmeter readings to get a fairly approximate value of the self-induction of the coil. As an instance the self-induction of a coil having a calculated value of 0·0018 henry worked out as 0·0023 henry, different determinations agreeing amongst themselves to within a few per cent. A Wehnelt's interrupter used in conjunction with a condenser is thus a very convenient device for producing from a continuous current a steady alternating current of moderately high frequency, by means of which all the ordinary phenomena of such currents can be readily studied. For example, it is a difficult matter *not* to get the Ferranti effect at the terminals of a condenser.—Yours, &c., ROBERT BEATTIE.

Owens College, Manchester, March 15.

NEUGSCHWENDER'S WAVE DETECTOR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of March 3 Mr. Fournier d'Albe abstracts from *Wiedemann's Annalen* an account of a remarkable kind of anti-coherer discovered by Neugschwender, depending on a film of moisture on glass whose resistance increases with the impact of electric waves.

But I conjecture that the action is really of the orthodox coherer kind, the continuous or semi-continuous film instantly aggregating into globules under electric influence, and so breaking the continuity.—Yours, &c., OLIVER J. LODGE.

GOVERNMENT TELEPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 10th there is an article on the Telephone Question, in which, referring to a statement I made in the House a few days ago, you say:—

"There may be some villages in America where a telephone service can be had for $15 a year, but in the aggregate the rates are, we believe, considerably higher than in this country. The average tariff in New York is far above that in London."

It is not a question of "villages" in the United States only having cheap telephone service. The following is a quotation from a letter which I recently received from a well-informed correspondent in reference to the telephone business in the States:—

"There are between 1,500 and 2,000 new telephone exchanges in operation in the United States, whose rates are from $1.50 to $3.00 per month, according to the size of the city or town in which the exchange is located. These are in opposition to the Bell."

The rates in New York are higher than in London, but the service is also much better. If you are unaware of why it is so dear there, your intimacy with telephony in the United States cannot be extensive. The high rates for service are maintained by bribery and corruption, and the facts have been exposed in the State Legislature again and again. It is this which afflicts telephone users in New York just as our standing affliction has been the Telephone Department of the Post Office. Where there is monopoly in America the rates are high; where there is competition, actual or possible, service is cheap and usually good.—Yours, &c.,

London, S.W., March 15. A. D. PROVAND.

CANDLE POWER EFFICIENCY OF INCANDESCENT BODIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: From experiments made with filaments composed of mixtures of various alkaline earths, I find that such filaments will burn in a vacuum. This is contrary to the statements made by Mr. Swinburne and others about the "Nernst" lamp. In fact, I find the same filament, when giving the same candle-power, requires less energy than it does when burning in the open air, and, moreover, that the difficulties of the mounts when such filaments are in a vacuum almost vanish.

I think the above facts are important, as I cannot imagine how it can now be said that the light of such filaments depends upon extra oxygen. This fact also, apart from other considerations, tends to show that such bodies are not electrolytes, for it appears that, with the same filament, they require the same voltage, whether they be run with alternating or continuous current, when either in a vacuum or in the open air.

A point of some interest is that such filaments, when run at the efficiencies given for the "Nernst" lamp, change so that the initial warming up temperature has to be gradually raised higher and higher, and I shall be glad to hear whether this point has been discovered and remedied in the "Nernst" lamp. There are many other points which, with the few tests I have already made, show that the production of such lamps is surrounded with many practical difficulties—chiefly in obtaining uniformity of voltage, candle-power and efficiency, and in obtaining good mounts; their increasing resistance and loss of candle-power when burning, &c.

Whilst dealing with the above subject I may remark that I cannot understand how it comes that there are so many theories advanced for the efficiency, light, &c., of incandescent bodies generally. It seems to be quite a simple matter. It is purely a question of temperature, with the "Nernst" lamp, as with carbon or any other body raised to incandescence. With a filament formed of alkaline earths one possesses a body which is a bad heat radiator; consequently, it does not require such a supply of watts or calories per second to maintain it at any given temperature. Again, with the alkaline earths we have bodies whose fusing point is extremely high (much higher than carbon); consequently, the temperature to be given to them can be much higher than to bodies whose fusing points are lower—in other words, a given quantity of such a body can be made to give a greater light, but at greater temperature, the said temperature requiring less watts or calories for its maintenance, owing to the body's bad radiating power. In the face of this I do not see the necessity for speaking about the exchange of oxygen, electrolytic effects, &c.—Yours, &c.,

Hammersmith, W., March 10. C. J. ROBERTSON.

PARLIAMENTARY INTELLIGENCE.

THE NEW LONDON ELECTRICAL BILLS.

The Select Committee of the House of Commons appointed to consider the scheme of the St. James's and Pall Mall Electric Light Co. for the extension of their works, commenced their inquiry yesterday (Thursday), Sir W. Coddington presiding. The other members of the Committee were Mr. Price, Mr. Clough and Mr. Cubitt.

Mr. Balfour Brown, Q.C., and Lord Robert Cecil appeared for the promoters; Mr. Freeman, Q.C., and Mr. Barclay, for the St. James's Vestry, Westminster, who were petitioning against the Bill; and private petitioners were represented by Mr. E. Boyle, Q.C., and Mr. C. A. Russell, Q.C.

Mr. BALFOUR BROWN, Q.C., said the object of the Bill was to enable the promoters to acquire lands and electric generating stations, and for other purposes. It was an almost exactly similar Bill to one which passed through both Houses of Parliament last year at the instance of the Chelsea Electricity Supply Co. (see *The Electrician*, July 29, 1898, p. 467). The promoting Company came into existence in 1888. For the first seven years they worked under a licence. In 1890 they got a provisional order by which their length of life was extended to 42 years from 1889. Of the £100,000 capital asked for at the start only 5,000 £5 shares were subscribed for, and the business had to be carried on by means of a loan of £35,000, afterwards increased to £50,000, on terms which gave the Debenture holders the option to change their Debentures for Ordinary shares. The present capital of the Company was £160,000 Ordinary shares and £100,000 Preference shares. The Company had begun their business at a place called Mason's-yard, but they had been obliged to go to Carnaby-street. The vibration, &c., at the former place had been complained of and the Court of Chancery had required them to abate the nuisance according to the requirements of the Board of Trade. There was no vibration at Carnaby-street. The demand upon the Company was so great that they could not meet it without acquiring land for the extension of their undertaking. It was found impossible to do this by agreement; therefore, they were compelled to come to Parliament for compulsory powers. Last year the Chelsea Company and the Metropolitan Supply Co. (Limited) secured somewat similar powers. There was an absolute necessity for the passing of the Bill. In 1890, when they began their business, they had 177 consumers, and in 1898, 1,400. There were now on their system 142,853 lamps, and whereas in 1891 they supplied 1,000,000 units of currrnt, in 1898 they supplied 3,448,000. The Company's plant only gave a surplus of 13 per cent., so that should there be a fog or breakdown the surplus might be easily exhausted. According to experts prudent working for safety should give them 25 per cent. surplus. The average price per unit obtained was 4·35 pence per unit, the authorised charge to which they could go if they chose being 8d. For public lighting they charged 2½d. per unit, which was a less amount than adjoining local authorities, who made their own electricity, could manufacture it for. The horse-power of the Company's engines now was 4,500. It was proposed to add 2,500 H.P. And, beyond this, it was proposed to put up transformers which would be constructed in connection with the generating station they were seeking to put up in conjunction with the Westminster Company on the banks of the Regent's Canal. He pointed out that on the previous day, when the fog was very bad, the Company used as much as 60 tons of coal, and were brought to the end of their tether so far as manufacture was concerned. Under the circumstances it was necessary to have a place where they could store coal, and that they should have the necessary generating capacity for making electricity. It was necessary to bring electricity to Carnaby-street. Referring to the opposition, he said the St. James's Vestry, Westminster, complained of the inconvenience of putting up such large works as those proposed in the West-end within 150 yards of Regent-street. In reply to that he pointed out that the promoters were anxious to avoid the construction of too large a generating station, and, therefore, they proposed entering into partnership with the Westminster company and constructing works on the Regent's Canal. It was complained that no provision was made for compensating the petitioners for damage which would be done to their roads and other property. This he did not understand, for the reason that all the mains in the streets were to be made not under the proposed Bill, but under a provisional order already in existence. The petition was a weak one. The Craven trustees and others, who were petitioners against the Bill, did not wish to sell their property, and therefore alleged that it was not necessary for the petitioners to extend their works at Carnaby-street. These petitioners would be dealt with satisfactorily under the Lands Clauses Act.

Mr. EUSTACE BALFOUR, Chairman of the St. James's and Pall Mall Company, gave evidence in support of the Bill. He said that the proposed works at Carnaby-street would only enable them to meet their requirements to 1901. If the whole of the new site were covered with works there would not be a sufficient supply to last ten years. The price charged for private lighting was 4·35d., and for public lighting 2½d. per unit. They hoped to decrease the power price to 2d.

Mr. SYDNEY DOBSON, Engineer to the company, said that at present they had 6,000 H.P. at work. In 10 years they expected to supply half a million lamps with electricity, and then they would require 15,000 H.P. This extension was necessary in order to avoid a breakdown of the existing supply. The supply of the Company had increased 15 per cent. per annum during the past two years. They anticipated a large increase in the motor business as soon as they could reduce the cost of current for power.

Sir FREDERICK BRAMWELL, C.E., said he had known the works of the promoting company for some time. They were admirably conducted, but of insufficient capacity, and the powers now sought were quite necessary.

Prof. A. B. W. KENNEDY also gave evidence in support of the Bill.

Mr. FREEMAN, Q.C. (for the St. James' Vestry), declared that the Vestry and owners of property would tell the Committee that there was at the present time inconvenience and nuisance both from smoke and vibration, and the fear entertained was that if Parliament allowed the Carnaby-street generating station to be enlarged, as proposed, the nuisance must inevitably be increased. The Company could make arrangements under their other Bill for generating all their electricity elsewhere.

The Committee adjourned until to-day (Friday).

LEGAL INTELLIGENCE.

Short and Others v. Viola.

An appeal was heard in the High Court before Lords Justices A. L. Smith, Collins and Romer, in which the plaintiffs appealed for judgment or a new trial in the action tried in November before Mr. Justice Wills and a special jury. The original action was brought to recover damages from the defendant, Mr. Otto F. Viola, for non-performance of an agreement. Verdict was given for the plaintiffs upon what counsel for the appeal said were the material issues, but for the defendant upon one issue. The plaintiffs were the Eureka Tempered Copper Co., of Pennsylvania, U.S.A., of which the plaintiff Short was chairman. The company in 1894 possessed secret processes for casting copper without alloys or blowholes, and for treating copper after it had been cast both for hardening or making it malleable. They employed a hundred hands and had agents in London. It was proposed to establish a branch in London, and defendant was approached, and became a party to an agreement by which he undertook

Digitized by Google

to form a company with £20,000 capital to take over the European rights and all European orders, the company receiving certain shares. On the agreement, the action went for trial, and plaintiff said there had been misdirection and a verdict against the weight of evidence. Plaintiffs alleged that they had been taken by surprise by defendant's evidence, and that the learned judge who tried the case had wrongfully refused to allow them to call rebutting evidence. The surprise evidence brought forward by defendant was that the plaintiffs had no secret process, and the plaintiffs declined in open court, "with reporters and representatives of electrical firms and analytical chemists present," to divulge their secrets; but they offered to hand up particulars of the secret process to the judge or the jury, and they desired to recall their chief witness, Mr. Short. This was, however, refused, and the verdict of the jury had to be taken as the case then stood. The English company was not formed.

Lord Justice SMITH (to Mr. Harris, Q.C., for the appellants): You refused to tell what your process is, and I think the jury might very well take the inference that you have no secret process at all.

Mr. HARRIS: It was offered to the judge and jury.

Lord Justice SMITH: I have never allowed that in a court of justice. The other side call evidence that you have no secret process, and you after that want to recall your witnesses. You ought to have had that evidence before.

Mr. HARRIS said plaintiffs refused, and he said rightly, to disclose their secret process in open court.

Lord Justice SMITH: You need not have gone into court.

Without calling upon the respondent's counsel, their lordships delivered judgment, dismissing the appeal with costs.

Lord Justice SMITH said the point taken by the defence was that there was no secret process at all, and consequently the agreement entirely failed to provide any consideration. Mr. Short, in the witness box, did not say what the secret processes were. He was within his rights, but he had no reason to be surprised at the effect of this upon the jury. The specific evidence before them was that there was no secret process at all, and upon all the circumstances as put before them the jury acted. In his judgment Mr. Justice Wills was right, and the verdict of the jury must stand.

The other Lords Justices concurred.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

"The Electrician" Electrical Trades' Directory and Handbook for 1899.—The "Big Blue Book" for 1899 is NOW READY. The Directory Division has been corrected up to Feb. 8, 1899, and all the latest new names, changes of address, &c., will be found included. The Handbook Division has been much extended, many valuable tables having been added. The volume contains, also, the large Sheet Tables of Electricity Supply Stations and Electric Railways and Tramways, finally corrected to Feb. 9, 1899. The price of the Directory and Handbook remains the same—10s., post free 10s. 9d.; abroad, post free, 12s. (United States 13s. 6d.).

TENDERS INVITED.

As announced in an advertisement, the *Barking* District Council invite tenders for the supply and erection of one 80-kilowatt steam dynamo, with necessary pipe-work and accessories. Plans, &c, may be obtained from the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C., after 11th inst., and tenders, addressed to the chairman of the Council, must be lodged at the Council Offices before noon of the 27th inst.

The *Sunderland* Corporation invite tenders for (*a*) india-rubber covered cables, (*b*) cast and wrought iron pipes and street service boxes, (*c*) stoneware casings and bearers, and (*d*) house fuse boxes. An advertisement contains further particulars, and specifications, &c., can be obtained on application to the borough electrical engineer (Mr. J. F. C. Snell), Dunning-street. Tenders, addressed to the Chairman of the Lighting committee, must be delivered at the office of the town clerk (Mr. Fras. M. Bowey), Town Hall, Sunderland, by noon of Thursday, 30th inst.

The *Plymouth* Corporation invite tenders for twelve months' supply, from April 1 next, of transformers and arc lamp carbons. Specifications may be obtained from the borough electrical engineer (Mr. John H. Rider), to whom tenders must be sent by 23rd inst. Further particulars are given in an advertisement.

The *Doncaster* Corporation invite tenders for the supply and erection of (*b*) three mild steel Lancashire double-flued boilers; (*c*) three sets of steam dynamos, two sets of larger steam dynamos, condensing plant, &c., and a 6-ton overhead traveller; (*d*) storage battery of 136 cells, having a capacity of 750 ampere-hours; (*e*) electrical instruments and other apparatus; (*f*) underground armoured cables, street boxes, &c. Further particulars are given in an advertisement, and specifications can be obtained from the consulting engineer (Mr. James N. Shoolbred), 47, Victoria-street, London, S.W., or at the office of the Borough Surveyor, Doncaster, after 14th inst. Tenders must be sent to the town clerk (Mr. Thos. B. Sugden) by noon of 28th inst.

The *Poplar* (London) District Board of Works invite tenders for the execution of the following contracts:—(*a*) Engine and pump room equipment and all electrical plant except battery; (*b*) boiler house equipment; (*c*) battery and battery stands; (*d*) public street lighting. Specifications, &c., may be obtained from the clerk to the Board (Mr. Leonard Potts), 117, High-street, Poplar, London, E., on and after 23rd inst. Further particulars of the Board's requirements are given in an advertisement, and tenders must be sent to Mr. Potts by 10 a.m. of Tuesday, 25th April.

The *Tynemouth* Corporation invite tenders for the supply and erection of the following plant:—(2) boilers, &c., (3) economisers and fittings, (4) ejector-condenser, circulating pumps, tanks and pipework, and water cooler, (5) pumps, feed pipes, &c., (6) travelling crane, (7) traction switchboard, (8) lighting switchboard, (9) accumulators, (10) cables, and (11) traction steam dynamo. An advertisement contains additional information. Specifications, &c., may be obtained on and after 20th inst., at the offices of the consulting engineers (Messrs. Lacey, Clirehugh and Sillar), 2, Queen Anne's Gate, Westminster, S.W., and tenders must be sent in to the town clerk (Mr. Horatio A. Adamson), by noon of Saturday, 15th April.

The Corporation of *Peterborough* invite tenders for the supply and erection of the following electric lighting plant:—(1) Lancashire boilers and economiser; (2) Steam dynamos, balancers and boosters; (3) Secondary battery and accessories; (4) Switchboard and instruments; (5) piping, tank, condensers and pumps; (6) insulated cables. Specifications may be obtained on application to Mr. John C. Gill, Municipal Offices, Peterborough, and tenders must be lodged with the town clerk (Mr. W. Mellows) not later than Thursday, 20th April. Further particulars are given in an advertisement.

The *Edinburgh* Corporation invite tenders for the supply and erection of water tube boilers at Dewar-place station. Specifications may be obtained from the resident engineer (Mr. F. A. Newington), and specifications, &c., may also be seen at (but not obtained from) the offices of Prof. Alex. B. W. Kennedy, 17, Victoria-street, London, S.W. Tenders must be delivered to the offices of the town clerk (Mr. Thomas Hunter, W.S.), City-chambers, Edinburgh, by Monday, April 3rd. An advertisement contains further particulars.

The *Aberdeen* Corporation invite tenders for the supply of:—(1) two Babcock-Wilcox boilers, (2) one 180-kilowatt steam dynamo (Belliss or Willans and Robinson engine), with steam and exhaust pipes, and one 75-kilowatt balancing set. An advertisement contains further particulars, and specifications, &c., may be obtained from the city electrical engineer (Mr. J. Alex. Bell). Tenders must be sent in to the town clerk (Mr. W. Gordon), Town House, Aberdeen, by April 5.

The *Paddington* (London) Guardians invite tenders for the wiring of the workhouse in Harrow-road. Tenders must be delivered before 5 p.m. of 28th inst.

The Electric Lighting committee of the *Rothesay* Town Council invite tenders for the supply and erection of two 20 H P. coupled engines and dynamos, switchboard, cables, arc lamps and posts, feed pump, steam and exhaust pipes, &c. Tenders to town clerk (Mr. John T. Wilson) before noon of Monday, 27th inst.

The Guardians of the *Poplar* (London) Union invite tenders for the supply and erection of (*a*) steam turbines and dynamos (direct coupled), (*b*) electric motors, (*c*) accumulators, (*d*) electric cables, wiring, &c., and (*e*) main switchboard and distribution boards. Tenders to Mr. G. H. Lough, before 6 p.m. of 22nd inst.

The committee of the *Stockport* Sunday School require tenders for the electric lighting of their premises. Applications for permission to view premises to secretary by March 24.

The *Southend* Corporation invite tenders for the temporary transfer of their provisional order. Tenders to town clerk by April 6.

The *Lewes* Corporation invite offers for the erection of electricity supply works. Tenders by March 24.

The *Bury* (Lancs.) Electric Lighting committee invite tenders for a Lancashire boiler with steam and other pipes. Tenders to Town Clerk by 20th inst.

The *Stockport* Corporation invite tenders for the supply, erection and maintenance for 12 months, of 36 continuous current arc lamps. Tenders to chairman of Gas and Electricity committee, by 23rd inst.

The *Beckenham* District Council invite tenders for construction of a dust destructor. Tenders to the clerk, by 27th inst.

The *Bristol* Corporation invite tenders for installing the electric light at the petty sessions courts and offices. Tenders to clerk by March 30.

Digitized by Google

The *Gillingham* (Kent) District Council invite tenders for wiring their Technical Institute. Tenders to clerk, Gardiner-street, New Brompton, by 23rd inst.

The *Plymouth* Corporation invite tenders for the supply of steam coal and lubricating oils (for 12 months). Tenders to borough electrical engineer (Mr. J. H. Rider) by 24th inst.

The *Halifax* Corporation require tenders for supplying 100 creosoted telegraph poles. Tenders to Clerk by 20th inst.

The *Aberdeen* Corporation invite tenders for the supply and erection of the following materials for the equipment of their George-street and Woodside tramway route :—(*a*) permanent way and roadwork, (*b*) overhead line construction, (*c*) feeder and test cables, (*d*) tramway cars and all accessories, and (*e*) switchboard, instruments, &c. Tenders to town clerk (Mr. W. Gordon) by 10 a.m. of 29th inst.

The Corporation of *Port Louis* (Mauritius) invite tenders for the exclusive privilege to establish and maintain electricity supply works in the town. Further particulars are set out in an advertisement, and tenders must be addressed to the Agent-General (Mr. M. Ulcoq), 9, Idol Lane, London, E.C., by noon of 23rd April. Conditions (in French) may be obtained from Mr. Ulcoq.

TENDERS RECEIVED AND ACCEPTED.

The following tenders have been received by the Leyton School Board for the electric lighting of the Kirkdale-road and Harrow-green schools :—

	Kirkdale-road.	Harrow-green.
— Digby	£464 11 6	£459 18 0
Westminster Engineering Co.	451 6 0	430 2 0
J. E. Spagnoletti and Crookes	449 15 0	418 0 0
Strode and Co.	427 0 0	417 0 0
Edmondson's Electricity Corporation	414 8 0	385 0 0
Moody Bros.	412 5 3	359 17 0
Allingham and Fennell	344 12 0	335 14 0
H. D. Barlow and Co.	341 3 0	333 3 0
Vaughan and Brown	327 0 0	306 0 0
W. R. Woodward	237 5 0	225 5 9
Vulcan Electric Co.	208 6 0	208 19 8
Architect's Estimate	385 0 0	360 0 0

The Aberdeen Town Council have accepted the tender of Messrs. T. Bolton and Sons for the supply of copper strip, 1in. by 25in. and 1in. by 2in.

The Inverness District Lunacy Board, who recently decided to introduce the electric light into the Inverness Asylum, at a cost not to exceed £5,000, have accepted the tender of Tangyes (Limited), for the supply of steam engines, that of Siemens Bros. and Co. for dynamos, and of Messrs. James White for the main switchboard. The lighting is to be carried out under the supervision of Dr. J. T. Bottomley, F.R.S.

The Birmingham Corporation have accepted the tender of the Birmingham Electric Supply Co., for substituting electric for gas lighting in the Council chamber at £1,774.

The Burnley Corporation have accepted the tender of Messrs. Williamson and Joseph for the supply of a switchboard.

The Exeter Town Council have accepted the tender of Babcock and Wilcox (Limited) for the supply of a 500 H.P. boiler at £1,120, and that of S. Z. de Ferranti (Limited) for supplying a 250-kilowatt steam alternator at £3,460.

The Electric committee of the Belfast Corporation have accepted the tender of Babcock and Wilcox (Limited) for the supply of water-tube boilers.

Messrs. Handley and Shanks have obtained the contract from the Dublin Board of Control for the electric lighting of the Richmond (Dublin) Lunatic Asylum. The plant will comprise two steam engines, dynamos and a battery of accumulators. The work will be carried out to the specification of Mr. Walter Leake.

The tender of Messrs. Laurence, Scott and Co. has been accepted by the Lincoln Corporation for the supply of engines, dynamos, &c., at £4,423.

The Aberdeen Town Council have accepted the tender of Messrs. P. C. Middleton and Co. for wiring the Art Gallery at £75.

APPOINTMENTS VACANT AND FILLED.

A thoroughly competent manager is required for large india rubber works to be established on the continent. Some further particulars are given in an advertisement.

The Folkestone Electricity Supply Co. require an electrician-in-charge. Applications to the engineer and manager (Mr. Thomas Hesketh). See advertisement.

The Corporation of Devonport require an electrical engineer competent to devise an electric lighting and tramway scheme for the borough. Salary £300 per annum. Further particulars are set out in an advertisement. Applications must be lodged with the town clerk (Mr. A. B. Pilling), by Wednesday, 29th inst.

The Bolton Electricity committee require two junior assistant engineers. Further particulars are set out in an advertisement, and applications must be sent to the borough electrical engineer (Mr. Arthur Ellis) by noon of 30th inst.

As advertised elsewhere, the Edinburgh Corporation invite applications for the position of assistant to the superintendent of mains. Applications to the resident electrical engineer (Mr. F. A. Newington), 5, Dewar-place, Edinburgh, on or before Monday, April 3.

We are pleased to announce that Mr. F. Harman Lewis, late borough electrical engineer to the Corporation of Wolverhampton, has been appointed to succeed Mr. H. Collings Bishop at Leyton, on the occasion of Mr. Bishop's transferring his services to Wigan. Mr. Lewis commenced the study of electrical engineering in 1883, when he entered as a student at Finsbury. In 1886 he entered the works of the Electrical Power Storage Co., where he remained for about two years. In 1889 he was for a time upon the staff of the Westminster Corporation, then for about two years an assistant engineer to the St. James' and Pall Mall Co., and in 1891 he was appointed electrical engineer to the Corporation of Hull, for whom he designed and carried out electricity works on the three-wire system, at the cost of about £35,000. He was appointed in 1893 electrical engineer to the the Borough of Wolverhampton, and designed and laid down an electricity works on the 2,000 volt direct current system, for private and public lighting, at a cost of about £40,000. He resigned from Wolverhampton in 1898.

BUSINESS NOTICES.

Official intimation will be made this week of the partnership entered into between Mr. W. H. Preece, C.B., F.R.S. (late engineer-in-chief to the Post Office), Major Cardew, R.E., ret. (for the past 10 years' electrical adviser to the Board of Trade), Mr. A. H. Preece and Mr. Llewellyn Preece, who will together form the firm of Preece and Cardew, consulting electrical engineers, 13, Queen Anne's-gate, Westminster, London, S.W.

Messrs. Gillies and Hornidge have taken City offices at 49, Queen Victoria-street, E.C., where future communications should be addressed.

Messrs. E. J. Everett and W. J. Cole (trading as Everett and Co.), engineers and electricians, 22, Charterhouse-square, London, E.C., have dissolved partnership. Debts by Mr. Everett.

The London offices of Messrs. Lacey, Clirehugh and Sillar, consulting engineers, have been removed to 2, Queen Anne's-gate, Westminster, S.W., where all future communications should be addressed.

Messrs. Handley and Shanks have opened a branch at 46 and 47, Corn Exchange-buildings, Fennell-street, Manchester. Mr. C. E. Hunter will act as representative.

Messrs. Woodward and Craig, electrical engineers, 69, Waterloo-street, Glasgow, have dissolved partnership. Debts by Mr. Craig.

Owing to increased demand for their goods the Electrical Co. has established, in addition to their Brighton branch, a branch establishment at 21, Corn Exchange-buildings, Fennel-street, Manchester, with Mr. A. V. Ward as manager. The Company state that at present they have on order machines aggregating nearly 2,000 H.P. The open and enclosed arc lamp department continues busy.

BANKRUPTCIES, LIQUIDATIONS, &c.

A receiving order has been made against F. Marson (trading as F. Marson and Co.), electrician, 1, Poplar-avenue, Leicester. The first meeting of creditors will take place on 21st inst. at the Official Receiver's, 1, Berridge-street, Leicester, and the public examination on April 7th at the Castle, Leicester.

A meeting of the Globe Electrical Advertising Syndicate (Limited) will be held at 1, St. Peter's Church Walk, Nottingham, on April 13 to receive an account of the winding up.

The application for the discharge in bankruptcy of P. C. Pope, electrical engineer, 6, Castle-street, Hapton, near Burnley, will be heard on May 20th at the Court House, Burnley.

The deed of assignment previously referred to in the matter of John Alfred Edmondson, electrical engineer, Leeds, has, we are informed, been assented to by creditors representing a large proportion of the liabilities. The solicitors who have the matter in hand anticipate that creditors will eventually be paid 20s. in the pound.

In the liquidation proceedings of New and Mayne, Limited, Mr. D. F. Basden, liquidator, 33, St. Swithin's-lane, London, E.C., notifies that deferred debentures of the International Engines Patents Development Co., Limited, are about to be issued to the creditors for the amount of their respective claims.

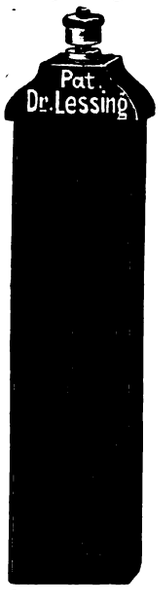
Digitized by Google

Salvage Sale.—Messrs. Wheatley Kirk, Price and Goulty have been instructed by the General Electric Co. to sell by auction on Wednesday next, March 22, a quantity of slightly damaged electrical stock, upon the premises, 203, Upper Thames-street, London, E.C., consisting chiefly of an extensive collection of electrical fittings and appliances damaged at the recent fire. Some further particulars are given in an advertisement. Catalogues of between 300 and 400 lots can now be obtained.

Sale by Tender.—Messrs. Fuller, Horsey, Sons and Cassell will offer for sale by tender, in one lot, a valuable leasehold engineering works situate at Barnsbury-street, Islington, London, N. The plant and machinery is practically new, and a portion of the contents will be found set out in an advertisement on another page. Tenders have to be sent in by noon of Thursday, March 23, to the Registrar of Companies (Winding-up), Bankruptcy Buildings, Carey-street, London, W.C.

Personal.—The personal friends of Mr. Ch. Gerhardi, manager of the Direct Spanish Telegraph Co., will entertain him at dinner at the Freemasons' Tavern, Great Queen-street, London, W.C., to-morrow (Saturday), the opportunity being taken to congratulate him upon receiving from the Queen Regent of Spain the appointment of Comendador of the Royal Order of Isabel la Católica.

Mr. George Gray Ward, vice-president and general manager of the Commercial Cable Co., has been elected president of the St. George's Society of New York, an important body of representative Englishmen in America. The position of president of this Society is regarded as a high honour.



A New Capped Carbon Plate.—The illustration below shows a new capped carbon plate, manufactured by Dr. Lessing at Nurnberg, whose agents here are Messrs. Krupka and Jacoby, of Watling-street, London, E.C. The introduction of a new carbon plate, which is claimed to be equal to any good capped carbon plate on the market, will be of interest to our readers.

Davy Improved Arc Lamp.—A demonstration was given a few days ago of the special features of the Davy improved arc lamp. The features are claimed to include perfect sealing, simple method of sealing, and ease of renewing the carbons and cleaning the enclosing bell, steadiness of running, whiteness of light, silence while running, long life, non-breakage of enclosing glass, and freedom from blackening, buckling and ash deposit. The lamp is said to be regulated for any current, and will run on direct or alternating current as desired, and in the latter case on any frequency without alteration. It will also run on series circuits. The lamp is 2ft. in length, and weighs only 14lb. complete with case and globe.

Resistance Materials.—We are asked to state that the "Beacon" high resistance material referred to on p. 694 of our last issue is not a new material.

Roller Bearings.—Owing to the large and increasing number of orders received by the Roller Bearings Co. (Limited), and owing to the difficulty in obtaining prompt delivery of material, which retards the completion of the bearings, the directors have made arrangements for enlarging the works and equipping them with improved machinery. The company report that their bearings, both large and small, are in very extensive use, and are giving excellent results, with the natural result that repeat orders are the invariable rule.

Electric Advertising Signs.—An advertising sign of new design, patented by Mr. W. T. Bell, of Nottingham, is exhibited in Oxford-street, London, at the corner of Tottenham Court-road. The sign has been erected by the Universal Electric Advertising Syndicate (Limited), who have acquired the Bell patents for this country, France and the United States, and we understand that arrangements are in progress for erecting similar machines in many large towns. We are informed that the sign consists of two sections, one below the other, each containing 504 lamps, so that the total number of lamps employed exceeds 1,000, although the total number in use for any one display rarely exceeds 300. It is possible to exhibit almost any number of advertisements successively, each being timed to appear for about 10sec., followed by 3sec. of darkness. An arrangement is introduced by which the lamps in each row light successively from the bottom upwards, producing the effect of a blind being drawn rapidly up, and exhibiting the particular wording desired. The construction of the electrical machinery, the controlling mechanism and the outside sign has been carried out by Messrs. Laing, Wharton and Down. The chief advantage claimed for the invention is that almost any advertisement or announcement may be made to appear at will without any alteration in the structure of the sign. The interior apparatus is compact, is entirely automatic, and is worked by an electric motor.

"Cost of Municipal Trading."—Price 2s. Messrs. P. S. King and Son, of Great Smith-street, Westminster, have issued in book form the Paper read before the Society of Arts by Mr. D. H. Davies, and the complete discussion thereupon, with interesting diagrams showing (1) the National Debt and local debt of the country, (2) the proportionate increase of rates and debt compared with population and valuation for 1878 and 1897, (3) the National Debt per head of population compared with the local debt, (4) the amount of local debt per £100 of rateable value, and (5) the proportion of local debt attributed to remunerative expenditure. An abstract of Mr. Davies' Paper has been recorded in *The Electrician*, and many of our readers may wish to possess the complete Paper and discussion on a subject which will in the near future require to be discussed and dealt with on the broadest lines. Much depends upon the manner in which this matter is handled, and a useful aid to a complete understanding of the development of municipal trading enterprise can be obtained from the publication under review. With Mr. Davies' deductions we are in general agreement, and, as many of those who joined in the discussion on the Paper are acknowledged leaders of men, the views then expressed upon this important question will prove of service to those studying the subject.

Alleged Infringement.—Mr. J. Slater Lewis, author of the well-known work, "The Commercial Organisation of Factories," recently brought an action against the *Mechanical Engineer* and John Heywood, publisher, Manchester, for infringement, and it is, in our view, to be regretted that Mr. Slater Lewis was not successful in his action. Without the lesson of this particular case, the time has certainly come when the property of authors and publishers should be better protected. It is a crying evil that no sooner is a book published which can fairly claim to be a standard work on the particular subject treated, than a pack of harpies set about clipping and carving the contents, and re-hashing them for publication either in cheap periodical or book form, just keeping clear of the all too lenient copyright laws. We write feelingly upon this subject, as we have been great sufferers; in fact, we have a case on hand at the present time where complete sets of articles, illustrations, and editorial remarks have been taken word for word, *en bloc*, without even the courtesy of acknowledgment. It is doubtful whether we can obtain any redress, and it is certain that if we obtained a verdict that is all we should obtain. From the remarks of Mr. Justice Cozens-Hardy in Mr. Slater Lewis's case, and from the statement we make above, it is manifestly time that some amendment of the law were brought about to protect technical experts from this wholesale piracy of their brain work. In the action brought by Mr. Slater Lewis, it was stated by the judge that use had admittedly been made of the plaintiff's book, and, in giving judgment for the defendants, the question was asked whether they demanded costs, and this question having been answered in the affirmative, Mr. Slater Lewis has the satisfaction of knowing that use has been made of his book without his permission, and that he has to pay handsomely for proving it.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from March 8 to March 14, with the ports of destination:—

Argentina—Buenos Ayres, £6. *Australasia*—Melbourne, £210 (telegraph material); Perth, £56; Port Chalmers, £28; Sydney, £158; Wellington, £26. *Austria*—Trieste, £178 (including £28 telegraph material). *Belgium*—Antwerp, £261; Ostend, £70. *Brazil*—Rio Janeiro, £490 (telegraph material). *Canada*—Montreal, £10. *Ceylon*—Colombo, £102. *Egypt*—Alexandria, £200. *France*—Boulogne, £112; Dunkirk, £250. *Germany*—Hamburg, £590. *Holland*—Amsterdam, £133; Flushing, £41; Rotterdam, £116 (telegraph material). *Hong Kong*, £14. *India*—Bombay, £432 (including £152 telegraph material); Calcutta, £1,920. *Italy*—Genoa, £500. *Japan*—Nagasaki, £2,151; Yokohama, £73. *Malta*, £450 (telegraph material). *South Africa*—Cape Town, £137; Durban, £98; East London, £26; Port Elizabeth, £1,517 *Straits Settlements*—Singapore, £25. *Sweden*—Stockholm, £44 (telegraph material). Total £10,424, against £19,555 in the corresponding week last year (March 9 to March 15).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Acton.—Messrs. Lacey, Clirehugh and Sillar have been appointed consulting electrical engineers to the Council, which has offers from three companies to supply electric current in the district—the British Insulated Wire Co., the London United Tramways and the Metropolitan Electric Supply Co. The latter offers current at 4d. per unit, provided the whole of the supply for the district be taken for a period of not less than five years, or at 3d. per unit for a term of not less than ten years.

Alleged Fraud.—At the Guildhall on Wednesday, Claude Vautin was again remanded, without bail, on the charge of obtaining valuable securities by means of false pretences.

Digitized by Google

Arbroath.—The Council have been informed that the Board of Trade have resolved not to expunge the clause from their Provisional Order giving to the Corporation power to hand over the electric lighting to a company. The Council, in conjunction with other local authorities and companies, intend to make a fight for the retention of the clause.

Bangor-Donaghadee Electric Tramways.—The County Down Grand Jury have approved the scheme of the Drake and Gorham Electric Power and Traction Co. for the construction of an electric tramway between these two towns at an estimated cost of £100,000.

Barnsley.—A tramways committee is to be formed to consider the advisability of constructing a system of electric tramways in the district.

The foundation stone of the new electricity supply works was laid on Thursday last by Councillor W. Brady.

Batley.—Messrs. Lacey, Clirehugh and Sillar have been appointed consulting engineers to the Town Council to prepare a report as to establishing electricity supply works and constructing electric tramways in the district.

Blackburn.—The Board of Trade have approved the new electric tramways of the Corporation. As soon as the lines are opened for traffic a reduction in the fares will be made.

Bradford.—The total income of the electricity department for the past half-year amounted to £13,011. 3s. 8d., an increase of £2,169. 3s. 1d. over the corresponding period of last year. The total expenditure, including interest and sinking fund, was £10,519. 10s. 3½d., an increase of £2,577, and the profit £2,491, a decrease of £407. The number of consumers was 850, an increase of 31 per cent., and the total units consumed, exclusive of current for trams, &c., has been 723,000, an increase of 31 per cent. The total profit since the opening of the works, after paying interest and sinking fund, was £20,882, while £10,556. 12s. 3d. had been set aside for depreciation, leaving £10,326 to be appropriated by the Council for distribution as it thought best.

Brighton.—In the accounts of the electricity department which were presented to the Town Council yesterday (Thursday), the income for the past year was given at £42,194. 11s. and the expenditure £22,846. 14s. 7d., leaving a gross profit of £19,347. 16s. 3d. Of this sum £147. 16s. 5d. has been appropriated to make provision for bad debts and £19,200 carried to net revenue account. Payment of interest on redeemable stock, loans, &c., absorbs £5,844. 2s. 9d. and sinking fund £6,553. 16s. 8d. leaving a balance of £6,802. 0s. 7d., which the Lighting Committee have, on the recommendation of the manager (Mr. Arthur Wright) allocated as follows:—

Relief of general district rate	£2,135
Depreciation of batteries	2,000
Depreciation of meters	1,000
Engineer's commission account	1,497

The balance (£170. 2s. 10d.) has been added to the reserve fund, which now amounts to £7,107. 14s. 3d. The income from the sale of current was made up as follows:—

820,985 units, at 7d.	£23,945	7	11
1,277,811 units, at 1½d.	7,986	6	3
56,475 at 7d. (public lamps)	1,647	3	9
493,430, at 1½d. do	3,083	18	9
Total	£36,662	16	8

The difference between this amount and £42,194. 11s. was made up by £3,437. 7s. 9d. for attending to public lamps, £366. 9s. 10d. for street lighting installation work, £947. 14s. 1d. for meter rentals, &c., £700. 7s. 8d. for work executed for customers, £58. 17s. 4d. brought forward, and a few minor items. There are now 257 public arc and 941 incandescent lamps. The quantity of electricity generated was 3,242,017 units, the total sold 2,648,701 units. During the year expenditure on capital account amounted to £25,652. 12s. 8d., bringing the total to £237,987. 3s. The total borrowing powers are for £290,881, and £67,726 is still unspent. The Committee have resolved, as from 1st Jan. last, to reduce the charge for current, after the first hour's consumption, from 1½d. to 1d. per unit.

The electricity accounts and the recommendations of the Lighting committee were duly approved by the Corporation.

Bristol.—The Council propose to purchase property adjoining the electricity works at Temple Back for £2,500 for carrying out extensions of the station building.

Cape to Cairo Telegraph.—It is announced that an understanding has been arrived at between the German Government and Mr. Cecil Rhodes as to the continuation of the Cape to Cairo telegraph through German East African territory.

Cardiff.—At Monday's Council meeting, Councillor Fox moved that "Proceedings be taken against Messrs. S. Z. de Ferranti (Limited) for the recovery of £2,112, penalties for the non-fulfilment of their contract for the supply and delivery of a new alternator on Sept. 15, 1896, at the electricity works, and which was not so delivered and has not been finally taken over by the electrical engineer up to the present time." After discussion an amendment was carried "That it be an instruction to the town clerk to take counsel's opinion as to whether it is advisable, and if so advised to take proceedings to recover damages from Messrs. Ferranti."

Chelmsford.—Mr. Robert Hammond has been called in by the Council to prepare a report upon the advisability of purchasing the undertaking of the local supply company.

Coatbridge.—As the British Electric Traction Co.'s Bill for the construction of electric tramways in Coatbridge and Airdree has been rejected, the Coatbridge Council have appointed a committee to co-operate with the Airdree Council in the preparation of a scheme to be carried out jointly by the two authorities.

Coventry.—The City Council have decided to modify their scale of charges for electric current to 6d. per unit for the first hour's maximum demand, and 3d. after.

Darfield.—Major Cardew has held an inquiry here into the application of the Council for a provisional order. It was stated that, with the exception of oil lamps, there was no illuminant in the district, and the desire for some sort of light in the streets was great. In 1897 the inhabitants held a meeting with a view to commemorating the Diamond Jubilee, and one of the things which was determined upon was the introduction of a system of electric lighting. Mr. William Johnson, engineer and manager of the Sheffield Corporation electricity department, said he estimated the capital expenditure necessary for the establishment of electricity works at from £8,000 to £10,000. The annual cost of maintenance and sinking fund would amount to about £1,175. The street lighting would require 121 16 c.p. incandescents. They would be able to supply nearly 73,400 units per annum for private lighting, which at 4d. per unit would produce £1,223. After evidence had been given in favour of the application, the Mitchell Main Colliery Co. and one or two other property owners opposed on the ground of expense.

Dundee.—The harbour engineer, who recently presented a report on the cost of lighting the harbour electrically, has been instructed to prepare a supplementary report as to the cost of lighting if the Board takes current from the Council's mains.

Exeter.—Acting upon the advice of their borough electrical engineer (Mr. H. D. Munro), the Council have decided to provide additional plant in order to be in a position to meet the anticipated increased demand next winter. The new plant consists of a 500 H.P. water-tube boiler and a Ferranti alternator of 250 kw. capacity. The entire cost of the extensions will amount to £5,350.

Exhibition.—An international motor car exhibition will be held at Berlin in September. Particulars from secretary, 1, Universitätsstrasse, Berlin, N.W.

Fire Tests.—A report has just been issued by the British Fire Prevention Committee upon a floor built by the Expanded Metal Co. (Limited). The object of these tests is to obtain reliable data as to the exact fire resistance of the various materials, systems of construction or appliances used in building practice.

Glasgow.—A conditional agreement has been entered into between the Corporation and the Kelvinside Electricity Co. for the purchase of the undertaking of the latter for £37,000.

In reference to the question of the generation of current for the tramways department, the Electricity committee have issued their report. Bearing in mind the gigantic proportions of the scheme of the tramways department, and the large amount of generating plant which will be required, it is evident (says the report) that no greater economy in the works cost of production is to be hoped for by combining the generating plants of the Electricity and Tramways departments, although there might be some saving in the cost of distribution; and, in view of the whole circumstances of the case, it is desirable, as a matter of expediency, that the tramways department should be entirely responsible for the whole tramways undertaking, including the generating and distributing plant and mains, if a system such as that recommended by their expert (Mr. Parshall) is to be carried out. The Electricity committee recommend that if the tramways department is entrusted with the supply and distribution of electricity for their own purposes only, they should be required to run all their mains, feeders, returns, and conductors, or leads of any and every kind, which may require to be laid underground in the space between and under the tramway rails.

Hampton Wick.—A committee has been formed to ascertain the terms of the Kingston Corporation for giving a supply of electric current to this district.

Harwich.—The Council propose to transfer their provisional order to the English Industrials (Limited), in consideration of the payment of £300 down. The Council also reserve the right to repurchase.

Huddersfield.—The Council have adopted recommendations to introduce electric traction on such sections of the tramways as the Tramways committee may decide, and to apply for sanction to borrow £100,000 for carrying out the work.

Digitized by Google

A resolution has been passed by the Council "that trading powers should be granted to corporations to administer the undertakings now possessed by them, and such other undertakings or concerns dealing with commodities required for the domestic or commercial convenience, and for the benefit of all classes of ratepayers, and that all trading should be subject to the proviso that local authorities should retain the absolute control of their streets."

Kendal.—Councillor Wakefield, at the last Council meeting, moved that the Council apply for a provisional order. He thought the matter had been under consideration long enough, and it was time some decided step should be taken. Eventually an amendment by Councillor Braithwaite, that the matter be left in the hands of the present sub committee, was carried. The committee had been making investigations, and they had obtained expert advice, which would enable them to make a report and present a scheme to meet the requirements of the town.

Leeds.—At the meeting of the Council on Friday it was decided to borrow a further £150,000 for extension of the electric lighting undertaking. Ald. Wigram said the Council wished to complete the existing station on the lines originally laid down, and that necessitated an expenditure of £33,500 on the present station, £46,000 on the increased mains, sub-stations and distribution, and £12,500 to provide for capital expenditure to Feb. 25, making £92,000. The increase of the output for this outlay was in the proportion of 7 to 4. This increase, judging by the past rate of demand, was estimated to last to Dec., 1900. When they had extended the lighting station, they would be able to supply an increasing demand, and give a continuous increase at the present rate. They would provide for that purpose, £25,000 for buildings and £33,000 for mains and machinery.

The Tramway committee propose to appoint a traffic manager to control the outside work of the tramways department.

Light Railways.—The Board of Trade have sanctioned the order for the construction of the Llandudno-Colwyn Bay light (electric) railway.

The United Service Tramways Co. propose to apply for power to construct a light (electric) railway between Roker (Sunderland) and Houghton-le-Spring.

The Light Railway Commissioners held an inquiry at the Guildhall, Westminster, on Wednesday, into the application of the Metropolitan Tramways Co. for power to construct light (electric) railways between Highgate, Finchley and Wood Green, and Finchley, Hendon and district. Mr. Pember, Q.C., who (with Mr. E. F. V. Knox) represented the promoters of the Finchley and Hendon railway, said a similar application was rejected in 1897, but the scheme had been somewhat modified. The line would start from Brondesbury, and, with a branch through Cricklewood, would run through Hendon, Finchley, Hornsey and Islington, to a terminus in the Archway-road near the terminus of the County Council's tramways. The line would be a little over 10 miles in length, and the cars would be driven by electric power on the overhead trolley system, and they would start with a ten minutes' service. The Islington Vestry are supporting the scheme. He stated that the scheme would cost £200,000.

Limited Liability Undertakings.—Notice is given that at the expiration of three months the names of the following electrical joint stock companies will be struck off the register :—

Akester Electro-motor and Accumulator Co.
Anders Telephone Co.
British Light Railways.
Denison Auto-telegraph Machine Syndicate.
Economic Electric Specialty Co.
"Electrical Plant."
Globe Electric Co.
Hermite British Electro Bleaching Co.
Lineff Electric Traction and Lighting Syndicate.
Mexican Gas and Electric Lighting Co.
New Electricity Supply Co., of Croydon.
Omnibus and Tramcar Electric Lighting Co.
Phœbus Electric Battery Syndicate.
Rogers Arc Lamp Co.
Self-generating Electric Vehicle Light Syndicate.
Tayler-Smith Electric Co.

London County Council—At Tuesday's meeting a resolution was approved :—"That it is expedient that the provisions of the Light Railways Act, 1896, for the construction of light railways, be put in operation in the suburban districts by the Council, either by itself or in conjunction with the other county authorities around London ; and that, with this view, the Highways committee be empowered to prepare and submit to the Council schemes for this purpose, and to negotiate with the other authorities with a view to joint action being taken."

Manchester.—The Council have decided to apply for sanction to borrow a further £500,000 for extensions to the electricity undertaking. Ald. Higginbottom said it was absolutely impossible to say how much money they would require in the future. Their business was increasing by leaps and bounds, and they were obliged to cater for an urgent public want. They had to wait several months for their last loan.

Metric System.—The metric system is to be introduced into the Russian Empire by the year 1900, the necessary arrangements being at the present time under the consideration of the various governmental departments.

Middlesbrough.—An inquiry has been held here into the application of the Corporation to borrow £36,000 for electric lighting purposes. The consulting engineer (Mr. Robert Hammond) submitted plans and gave technical details of the Corporation's electric lighting scheme. There was slight opposition as to the proposed site of the works.

Partick.—Owing to the Glasgow Corporation having provisionally acquired the undertaking of the Kelvinside Electricity Co., the public inquiry fixed for yesterday (Thursday) into the application of the company for a Provisional Order has been postponed.

Private Bill Legislation.—The London County Council propose to introduce a Bill for power to reconstruct and alter any tramways which have been acquired by the Council so as to adapt the lines for electric traction, to work the tramways electrically, to acquire land for a generating station, &c.

Provisional Orders Not in Operation.—In the House of Commons, on Friday, Mr. Ritchie stated, in reply to Mr. Thomas Bayley, that there were 30 local authorities who had obtained provisional orders for electric lighting who had taken no steps to give effect to the orders within the prescribed time. Besides these there were 63 authorities who obtained orders in 1897-98, and who had apparently done no work ; but the time prescribed had not yet expired. The Board of Trade had called the attention of local authorities to the matter, and had informed them that the Board proposed to consider the question of revoking the orders. In nearly all these cases the local authorities had replied that they were now taking steps to put the orders into execution.

Radcliffe.—A conference of representatives of the Radcliffe, Little Lever, Prestwich and Whitefield District Councils will be held to consider the question of joint action in order to provide electricity supply works for, and to construct electric tramways in the districts named.

Plymouth.—An inquiry was held here on Friday into the application of the Corporation to borrow £9,000 for the erection of a refuse destructor at Prince's Rock. The destructor is to be worked in conjunction with the electricity supply works. The borough electrical engineer (Mr. J. H. Rider) stated that the electricity department were prepared to take steam power to the extent of 150 H.P. from the destructor immediately, for which they would pay £830 per year. It would cost them more than that to generate the power themselves. By the time the destructor was completed, he hoped they would be in a position to take the full amount of steam from the destructor to the value of about £1,500 a year.

Swansea.—Modifications of the electricity supply scheme were approved by the Electric Lighting committee on Wednesday. The capital expenditure involved by the modified scheme is estimated at £24,648.

Telephone Trunk Extension.—Telephone trunk communication has now been established with Huntingdon, Peterborough and Stamford.

The Telephone Abroad.—An interesting series of reports respecting the telephone service in various foreign countries has been issued. The reports were prepared by the British Consuls in response to a circular from the Foreign Office setting out a series of 23 points upon which information was requested in answer to an inquiry in Parliament by Mr. A. D. Provand. A large amount of valuable information concerning the telephone, its inception, installation and working, is included in these reports, which mark a distinct advance in this class of publication. Whatever views may be held regarding the action of Parliament in dealing with the telephone question in this country, the publication of these consular reports is both opportune and useful. The consolation or satisfaction to be derived from these documents by advocates of municipal control and competition in telephone enterprise by the experience of other countries is doubtful, but we commend their careful perusal by all interested in the subject, prior to the second reading of the Government Bill in Parliament. If by their aid Members of Parliament are brought to carefully consider the intricacies of this telephone business, the publication of these reports will have served a very useful purpose.

Wakefield.—The revenue of the electricity department for the past year amounted to £2,318, and the expenditure to £1,135. After allowing for interest and sinking fund (£1,054) there was a net profit of £129 on the first year's working, a highly satisfactory result, upon which the engineer (Mr. J. K. Brydges) and Electric Lighting committee are to be heartily congratulated.

Workhouse Lighting.—Electric lighting is to be adopted at the Halifax Workhouse at an estimated cost of £1,000.

Digitized by Google

Worcester.—The accounts of the electricity department, an abstract of which was given in our last issue, were presented and approved at the meeting of the City Council last week. Contrary to custom, the discussion was of a harmonious character, and, instead of indulging in personal recriminations, members took to congratulating one another on the pleasing prospect of a profit on this year's working.

Wormit (Dundee).—This village is now lighted electrically. Incandescent lamps are employed. Current was switched on for the first time on 8th inst.

Electro-Harmonic Society.—A smoking concert will be held at the St. James's Hall Restaurant, Regent-street, London, W., on Friday, March 24, at 8 o'clock.

COMPANIES' MEETINGS AND REPORTS.

Metropolitan Electric Supply Co. (Limited).

The twelfth ordinary general meeting of this Company was held on Tuesday at Winchester House, Old Broad-street, under the presidency of Sir JAMES PENDER, Bart., M.P.

The SECRETARY (Mr. E. Cunliffe Owen) having read the notice convening the meeting.

The CHAIRMAN said: Gentlemen, I presume you will, as usual, take the report as read. I desire to express my regret that, owing to the serious illness through which our chairman, Sir Eyre Shaw, has passed, he is not present to-day, and it has, therefore, devolved upon me to preside on this occasion. I feel sure our chairman will receive the sympathy of all the shareholders, and that you will give me every support. Since we last met we have to deplore the loss of Dr. John Hopkinson, who, as one of our consulting engineers from the inception of the Company, rendered us the greatest help in all the many technical questions upon which he was called upon to advise. The report and accounts fully show the Company's position during the period with which we are dealing. Turning to the capital account, our capital has been increased by the issue of 22,500 shares. Many shareholders have written to us in reference to this issue, but I think you will readily call to mind that these shares were subscribed for at par by the holders of Founders' shares in consideration of the rights of those shares having been cancelled, in accordance with the arrangement come to in June last. The shares, Nos. 1 to 100, which were formerly Founders' shares of the nominal value of £10 each, now rank as Ordinary shares of like value but without any special privileges attaching thereto. The additional capital thus issued and upon which up to the end of the year £118,530 had been paid, has been almost entirely expended on mains and on our new Willesden works. With regard to these works an Act was obtained during last session, authorising us to erect these works, and this Act also gave us power to lay our mains along the towpath of the Grand Junction Canal Co., we having previously entered into an agreement with that body for that purpose. At one time we hoped that it might have been possible to have had the assistance of these works to relieve the strain of the past winter's supply. This, however, is not practicable, and we have no doubt in the long run that it will be found advantageous not to have been tempted to unduly press forward the works, and ample time will now be available for perfecting this important undertaking, as we are now aiming for the completion of the first portion in the early part of the summer in order that the plant may be in thorough working order to cope with next winter's demand. With regard to our expenditure on mains, this, in addition to our normal extensions, has been largely caused by the change we are gradually making in our system of supply. The unfortunate fire which occurred at Manchester-square last summer considerably delayed us in this work, the necessity for which, from the point of view of economical working and distribution, has already been explained to you, and is becoming increasingly urgent. The only other item in capital expenditure to which I think it is necessary to allude is the heavy item of parliamentary expenses. A portion of this expenditure was entailed in connection with our Willesden Act, and the remainder through our having been forced to defend—and, I am glad to say, successfully defend—our property in Marylebone. To this I shall refer again.

The revenue account shows that we have had a very considerable increase of business—an increase not altogether shown by the growth of revenue receipts. This is accounted for by the large reductions we found it necessary, as a matter of policy, to make in our rates of charge to customers. In addition to the desirability of conciliating local authorities, we had to meet actual competition in some districts, and to provide for a contingency of possible competition in others, before the alteration in our system of distribution and the completion of our new generating works had placed us in a position to make this reduction profitably. This, gentlemen, is the principal reason of the reduction in the dividend. This is also the principal explanation of the increased proportion of revenue expenditure to gross income, although the fire at Manchester-square, and the serious trouble of the Welsh coal strike, have also had an important share in the increase of expenditure. The coal strike was a serious matter, as it not only entailed the use of unsuitable and expensive fuel, but has left behind it a legacy of increased prices, which, we fear, will be maintained for some time to come. I ought to express our thanks for the assistance rendered to us by other supply companies, by which we were enabled to supplement our own supply during the exceptional period under review. With regard to this coal expenditure, I assure you the Board are fully alive to the absolute importance of effecting every possible economy in this direction. It is wholly in view of this necessity that our original system of distribution, admirably adapted as it was for pioneering work over a very large district like ours, but unsuitable after the business has developed and demand has become general, is being changed. These changes, coupled with the decreased works cost which we may hope to attain at Willesden, will, the board are confident, ultimately place the Company in a position to cope profitably with any requirements which may arise. The changes I have indicated, and the completion of our works, all point to the necessity of further capital issues. It will be seen from the accounts that we have funds in hand sufficient for immediate requirements, but it will probably be found necessary to make some further issue of capital during the year, and the board, happily now unhampered by the special interests of different classes of shareholders, will be able to take such measures as will best serve the interests of the Company as a whole.

The number of lamps connected during last year is a larger one than in any previous year. This is mainly accounted for by the reductions we have made in our charges; but, quite apart from this, there is no doubt that the use of electric energy is becoming yearly more general, and more a necessity. It is now my pleasing duty to refer, in a few words, to the work of our staff during a time of exceptional strain and difficulty; for, with this very large increase of lamp connection, and without the hoped-for assistance from Willesden, some of our stations were severely taxed, and we ought to acknowledge the skill, care and vigilance of our officers in successfully coping with this exceptional state of affairs. Gentlemen, we should have preferred to have been in a position to recommend at least a similar dividend to that of last year; but as, in addition to the reasons which I have given, the board are in agreement with your auditors, that it is necessary to build up the nucleus of a strong depreciation and reserve fund, they have not felt justified in exceeding their present recommendation. They are, however, fully confident in the soundness of the Company's position, and look forward to the time when the rate of dividend paid last year will not only be again reached, but exceeded. In conclusion, I should like to say a few words respecting the stiff fight which we had in Parliament last session to protect our property against the application made by the Marylebone Vestry to obtain competitive powers of supply against us. I scarcely like, from this position, to criticise too closely the unfortunate and mistaken policy which that Vestry has adopted towards this Company. While freely admitting that their action was dictated by a desire to serve the interests of the ratepayers (of which, however, I may mention that we are numbered among the largest), we rejoice that Parliament has decided to protect the interests of investors against what we consider to have been a most dangerous attack upon the security of capital. I trust that this policy will in future be respected as a precedent, and I shall certainly do my best to uphold it. I now move that the report and accounts be adopted and that the dividends be declared as set out in the report.

Admiral of the Fleet Lord JOHN HAY, G.C.B., seconded the motion.

Mr. CONWAY BISHOP said he thought the Company's accounts compared rather unfavourably with those of, say, the Westminster Company. He had been a shareholder in both for some years. The cost of generation of electricity last year was 47½ per cent. in the Metropolitan Company against 24 per cent. in the Westminster Company, while the Metropolitan Company's lamps connected numbered 430,000 against 339,000 in the Westminster, the cost of coal in the Metropolitan Company was £45,000 against £14,000 in the Westminster Company, and this seemed to him a large difference.

Mr. YOUNG said he was a large shareholder in the Company, and in most of the London companies which were paying dividends. He also thought that the Metropolitan Co.'s accounts compared unfavourably with those of the other companies. He thought 5 per cent. a miserable dividend as the life of their Company was limited, and they had a comparatively short lease, at the expiration of which they would be taken over without any allowance for goodwill, and at only the then value of plant. They would, in fact, be treated exactly as the Telephone Company was being treated now. Unless great care was exercised, the shareholders would be in a serious position at the end of their term.

Mr. JEFFREYS said he was somewhat in agreement with the criticisms passed, but he did not think either of the previous speakers had done justice to the difficulties with which the Board had had to contend. They would shortly be having the Willesden station to assist them, and he understood that that would enable them to cope with their difficulties. He thought the Directors had done great things in the past year, and had been very successful in defeating the action of the Marylebone Vestry.

Mr. JOHN NEWTON could not at all agree that the Company was in anything like a serious position, as had been argued by some of the speakers. A few years ago he bought some shares in the Company at 7½, he might have sold them since at 22, and they were even now at 17 or 18, and he, therefore, thought investors at any rate should be satisfied. He desired to support the Board in what they had been doing. He regarded the prospects of the Company as excellent. They had debited revenue with a large outlay for maintenance of all their works, and he did not see why they should continue to put a large sum aside for depreciation.

Mr. BALDWIN asked for some particulars of an item on the credit side of the revenue account relating to the rental of meters, which had decreased from £9,575 in 1897 to £4,478 in the present accounts.

The CHAIRMAN, in reply, assured the several speakers that the Directors had listened with great attention to what had been said, and were as anxious as the shareholders that the working of the Company should be successful. They were constantly endeavouring to obtain new business. With regard to the distinctions drawn between the Metropolitan and Westminster companies, he would ask Mr. Frank Bailey to reply, and that gentleman, who had been longer connected with the Company than he had, would explain the reasons why they could not work as economically as the Westminster and some other companies. Owing to severe competition in the Strand district they had been

Digitized by Google

obliged to reduce their charges in many ways, entailing a serious loss to them in respect to the payment of dividend; in fact, the loss on the sale of current and meter rentals came to a dividend of about 2½ per cent., and they had lost by the extra expenditure of coal a dividend of ½ per cent. If these changes and charges had not had to have been made the Directors would have been able to pay this year a dividend of 8 per cent. The Directors did not regard 5 per cent. as a splendid dividend, and hoped to present next year as good a record as in previous years. They looked forward with hope to the assistance of the Willesden station. The amount of bad debts actually written off last year amounted to £2,100, a very large sum, which they were taking every step to reduce.

Mr. FRANK BAILEY said the Company originally started with very ambitious aims. They had a district of 4½ square miles, whereas the Westminster Company started with only 2 square miles. At that time, too, the Directors were very anxious to adopt not only the best system for ultimate use, but that which would cost the least capital outlay. Of course, theirs was not quite a commercial undertaking in the ordinary sense. They were a company with Parliamentary obligations, and they had to supply any customer with current who required it in any portion of their area of supply. As the shareholders were aware, they started with the alternating high-pressure system which was adopted in order to secure the possibility and feasibility of pioneering such a large district, and they had succeeded he thought satisfactorily in this. They could supply any customer who applied for current, but they did this at high working cost. The criticisms of the shareholders were based on percentages, a very useful but a rather misleading procedure, unless great care was used. The percentages referred to at the meeting were naturally based on revenue—unfortunately he meant bearing in mind the percentage—but fortunately in view of the future of the Company. The Chairman had pointed out how they had been affected to the extent of 3 per cent. in the dividend. When, therefore, they debited works costs with such a large decrease of revenue, they were doing an injustice to the staff. With regard to the question of coal, they, of course, did not use more than they could help, but he must again draw their attention to the fact of the system which was adopted in connection with this matter. They had had to use the system, as it cost the least capital outlay in the first instance, and, therefore, they could not derive the same economical results from a small as from a large capital. Had they started with the most economical system their capital instead of being £1,000,000, would now have been £2,000,000 or £3,000,000. They would in that way have got the same economical results, but their returns would have been the same. They had now got the Willesden station, and he was perfectly satisfied that they would be quite contented in future.

Sir Eyre M. Shaw, Sir James Pender, Bart., M.P., and Mr. J. Verity were re-elected Directors, and the auditors, Messrs. Deloitte, Dever, Griffiths and Co., reappointed.

A vote of thanks to the Chairman, Directors and staff was carried unanimously, and, having been acknowledged by the Chairman, the proceedings terminated.

Bournemouth and Poole Electricity Supply Co. (Limited).

The second ordinary general meeting of this Company was held on Monday, March 13, 1899, Mr. AYMOR H. SANDERSON (Chairman) presiding.

The SECRETARY (Mr. H. B. Renwick) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, this is the first annual meeting of the Company, and your Directors have great pleasure in submitting to you the report and statement of accounts for the year ended December 31st last. This pleasure is much enhanced by the fact that they are able to show results even better than those anticipated by the prospectus which was issued by this Company in December of 1897. Before proceeding to refer to some of the items in the account, it is my duty to mention the retirement of Lord Rathmore, our late Chairman, and to express to you the great regret that the Directors and I myself feel, that his lordship has found it necessary, in consequence of the many calls upon his attention, to retire from this board. From the balance-sheet you will see that our assets are represented by investments of £4,000 in 2¾ per cent. consolidated Government stock, by £51,108 in shares of the Bournemouth and District Electric Supply Company, and loans on security to that company amounting to £63,891. In all, the amount invested by this Company is £119,000. The premiums on the first issue of shares have been applied towards writing off the preliminary expenses, and the remaining balance of £18 has been written off out of the revenue of the past year. The only expenditure made by the Company on capital account during the year has been the expense of applying to the Board of Trade for a provisional order for the districts of Christchurch, Pokesdown, and neighbourhood. These include a rapidly-increasing area which will, if we are successful in our application, form a most valuable asset of the Company. The only other item I have to refer to on this side of the account is sundry debtors £4,431, which consists mainly of interest, &c, due on December 31st to this Company from the Bournemouth and District Electric Supply Co., but that has since been considerably reduced. On the other side of the account you will see what are the liabilities of the Company. I should mention that our authorised capital is £150,000. That consists of 6,000 Four and a-Half per Cent. Preference shares of £10 each, and 6,000 Ordinary shares of £10 each, making together £120,000, and we have a balance of shares still unissued, amounting to £30,000. I will turn to the revenue account, by which you will see that the total receipts for the year have been £6,103, and that, after deducting our expenses of about £91, we have carried the balance amounting to £6,013 to the net revenue account. We have paid an interim dividend on the Preference shares at the rate of 4½ per cent. per annum up to June 30, 1898, amounting to £1,240; and we have also paid a final dividend on those shares to December 31st last, which leaves a balance of £3,469 available for distribution now. Out of this amount your Directors recommend that a dividend at the rate of 4 per cent. on the Ordinary shares, less income tax, be now declared, which will absorb £2,262, and leave £1,206 to be carried forward to the next account. Well, now, gentlemen, I have very little to add except to point out to you that, in the opinion of your Directors, we possess a very valuable property indeed in holding, as we do at the present time, the whole of the capital of the Bournemouth and District Electric Supply Co. The progress of that Company is evidenced in the fact that during the past year there has been connected the equivalent of 8,752 8 c.p. lamps, as compared with the equivalent of 3,482 during 1897. You will observe that these are record figures in the history of the Company, and although it is perhaps too much to hope that we shall continue to make the same rate of progress every year—still, we have very great faith that we have a most valuable and increasing property in the Bournemouth and district undertaking. I must just call attention to the fact that there is an application before the Board of Trade for the transfer of the undertaking now held by the Bournemouth and District Company to this Company, and as we now hold, as I have previously said, the whole of the shares in that Company, there would appear to be no reason whatever why any opposition should be offered to that transfer. We have, therefore, every reason to think that the Board of Trade will grant our application, and that when this transfer has been effected it will considerably decrease the amount of our administrative expenses. I do not think, gentlemen, that I have anything to add to what I have told you, but I shall be very pleased to answer any questions which may be asked on the subject of the report and accounts. I now move the adoption of the report and accounts.

Mr. J. ATKINSON HOSKER, in seconding the motion, congratulated the shareholders upon the progress made during the past year and upon the rosy prospects of the Company. He wished to say that the shareholders were to be congratulated upon the valuable officers that they had. They had a secretary, Mr. H. B. Renwick, and a staff, whose hearts and souls were most thoroughly in their work, and he felt certain that, much as they could congratulate themselves upon the past year's working, they would, as years rolled by, have to congratulate themselves still more in the future.

Mr. ORDISH mentioned that a certain amount of publicity had been given to the action of the Bournemouth Corporation in seeking to obtain a Provisional Order, and he should like to know whether this Company would be affected, in any way, by what that public body proposed to do.

The CHAIRMAN: We have given this subject full consideration, and I may say that we have not the slightest fear with regard to the result of that application to the Board of Trade.

The resolution was then carried unanimously.

The payment of the interim dividend on the Preference shares, at the rate of 4½ per cent., was confirmed, and a dividend on the Ordinary shares at the rate of 4 per cent. for the year was declared.

The retiring Directors, Mr. J. A. Hosker and Mr. F. W. Reynolds, were re-elected, and the auditor, Mr. R. H. Marsh, was re-appointed. The Directors' remuneration for the 12 months ended December 31 last was fixed at £300, with a similar amount for the year 1899, but in the event of the Company taking over, during the year, the undertaking of the Bournemouth and District Co. the amonnt is to be increased to £500.

A vote of thanks to the Chairman, Directors, secretary and staff was unanimously accorded, and the proceedings terminated.

Dover Electricity Supply Co. (Limited).

The fifth ordinary general meeting of this Company was held at Dover on Wednesday. In moving the adoption of the report and accounts, the Chairman (Sir William H. Crundall), said that they showed a material improvement in the Company's position. He reminded the shareholders that five or six years ago it was mooted that the municipal authorities should take up the supply of electric current in the town, he then holding the office of Mayor. He could not persuade some of his colleagues to do this, but was determined that the town should have the benefit of electricity supply. It therefore became his duty to cast about for the means of finding capital for the new enterprise. Through the Brush Company and the County of London and Brush Provincial Co. capital had been found, and the handsome and substantial building in which they were at present had been erected and equipped with all the necessary plant, mains, &c. At Eastbourne the Corporation had just agreed to take over the electric undertaking at something like 160 per cent. above the capital outlay, and knowing Eastbourne, he thought he might say that the Dover station was a better one, and that they had got a very valuable property, capable of enormous development. No doubt they would have heard that there had lately been a movement in Dover to take over their concern, but it seemed to him that the Company could have no desire for negotiations—at any rate, on the present basis of its earning power. For 1898 a 2½ per cent. dividend would have been able to have been paid on the whole capital employed, but for the fact that a considerable amount had had to be paid for interest on advances. These advances would now be paid off, the whole of the share capital having been issued, and a premium as high as £1 per share had been obtained on some shares dealt in. He hoped that they would earn and distribute a considerably larger percentage in respect of the present year. There was practically no limit to the amount which they could pay in dividends, and he hoped that it would not be long before they were paying, say, 12½ per cent., which they could do without reducing their present rate for current. He might remind the shareholders that any sale on the part of the Company for the next 12 years would be entirely a matter of negotiation, and even then, though compulsory, the undertaking would have to be bought as a going concern. The progress of the Company had been exceptionally good; a loss of £950 on the first nine months' working in 1895 was reduced in 1896 to a loss of £450; in 1897 the profit was

Digitized by Google

£1,100, and in 1898, as they would see, the profit had risen to £2,200. The Corporation, if they desired to take over the concern, would have to pay a very heavy premium. The further capital expenditure in 1898 had been for the purpose of meeting the increased demand, and he hoped that still further calls for expenditure of capital would be necessitated for the same reason. The lamp connections at the end of the year had been approximately 12,500. The plant capacity had been raised in 1898, so that it would deal with about 26,000 lamps connected. A contract had been entered into for the supply of light, and probably a certain amount of power to the contractors for the National Harbour. In addition to this the applications for ordinary lights had been 50 per cent. more than those received in the corresponding period of last year. He desired to thank the staff for their services. The report was then adopted, and the retiring Directors were re-elected.

British Electric Traction Co. (Limited).

The report of the directors of this company for the year to Dec. 31 last, just issued, is as follows:—

Capital Account.—During the year the directors have issued 10,000 Six per Cent. Cumulative Preference shares of £10 each at £12. 10s. per share, and £100,000 debenture stock at £116 per cent. The whole of the premiums (after deducting expenses), amounting to £29,135. 15s. 8d., have been placed to reserve, invested in Consols. Since the closing of the books further issues have been made of 20,000 Preference shares and £100,000 debenture stock. The proceeds of these issues will be brought into the next account. The subscribed share and debenture capital is now £300,000 in Ordinary shares of £10 each, £300,000 in Six per Cent. Cumulative Preference shares of £10 each, and £200,000 Five per Cent. Perpetual Debenture stock—total, £800,000. The whole of the present authorised share capital having been subscribed, the directors recommend that powers be taken to increase the nominal capital by the creation of 60,000 shares of £10 each; and notice is given of an extraordinary meeting to consider and pass the necessary resolutions.

Profit and Loss Account.—The gross profits, including £9,804. 9s. 6d. brought forward (but without taking into account the premiums of £29,135. 15s. 8d.), amount to £77,999. 14s. 7d., and, after deducting the expenses chargeable to revenue, the expenses incurred in connection with schemes not proceeded with and written off, and interest on debenture stock, there remains a net profit of £67,778. 13s., which the directors propose should be applied in writing off the remaining portion of preliminary expenses (£5,879. 1s. 8d.), reduction of goodwill account by £5,000, interim dividend at the rate of 6 per cent. per annum on Preference shares to Aug. 15, 1898 (£1,195. 16s. 8d.), dividend at the rate of 6 per cent. per annum on Preference shares, due Feb. 15, 1899, accrued to Dec. 31, 1898 (£2,252. 1s.), dividend at the rate of 6 per cent. on the Ordinary shares for the year (£18,000), and to carry forward £35,451. 13s. 8d.

Contracts and Undertakings.—Arrangements have been made for the adoption of electric traction in various localities. In some cases agreements have been entered into for the purchase or leasing of existing tramway undertakings, while in others parliamentary powers or orders under the Light Railways Act have been secured or applied for. Some of these arrangements have been made in co-operation with other parties. The total amount expended on works, and in negotiations and promotions (after deducting costs of undertakings which have been sold or transferred, and after writing off expenses incurred in respect of schemes or contracts not proceeded with) is £157,730. 17s. 7d.

Investments.—The company holds shares and debentures (which cost £420,731. 2s. 11d.) in a large number of existing tramway and analagous companies, and in some instances the majority of shares, with a view to the further development of the company's business and the adoption of electric traction. (Particulars of most of these associated companies are given in an appendix to the report.) An income of £11,853. 15s. 10d. has been derived from investments, but a large proportion of the amount appearing under this head was not so employed until the latter part of the year.

Annual Meetings and Accounts.—In order to include the results of the working and the accounts of the associated companies, which are generally made up to Dec. 31, in the annual report and accounts of the company, the directors propose that in future the accounts of the company should be made up to March 31 in each year.

Direct Spanish Telegraph Co. (Limited).

The report of the directors of this Company for the year ended Dec. 31 last states that the accounts show, after providing for interest on, and redemption of, Debentures, a balance to credit of revenue of £11,843. 18s. 9d. After adding the usual £5,000 to reserve, the directors recommend the declaration of dividends for 1898 of 10 per cent. on the Preference and 4 per cent. (free of tax) on the Ordinary shares, absorbing £5,486. 4s. Half this amount was distributed on Oct. 1 last, as an interim dividend in respect of the half-year to June 30. The balance of £1,357. 14s. 9d. is transferred to contingencies account.

The traffic receipts show an increase of £3,812. 15s. 5d., compared with 1897. The ordinary working expenses were £349. 3s. 8d. in excess of those for 1897.

On May 21 a fault was discovered in the Bilbao cable at about 13 knots from Bilbao. Although this fault did not interfere with the communication it was thought prudent to remove it, and this was effectually done on June 23. On July 8, the Bilbao cable broke at a distance of 199 knots from Falmouth, and was repaired on July 14. In both cases the repairs were promptly executed by cable ships of the Eastern Telegraph Co. The cost of these repairs, viz., £2,117. 11s. 3d., is charged to revenue. The cost of fitting extended premises in Gracechurch-street, London, for the Company's purposes (£961. 5s. 3d) is also charged to revenue.

South London Electric Supply Corporation (Limited).

In the second annual report of the directors of this Company it is announced that good progress has been made in developing the Coporation's undertaking. The buildings, including dust destructor, are nearly completed. The boilers are in position, and steam pipes, electrical plant, storage batteries, engines and steam alternators should be delivered in a few weeks. Permanent offices have been erected at the works, and the temporary offices will be vacated on 25th inst.

After thoroughly investigating the probabilities of finding water, the directors decided upon sinking an artesian well at the Corporation's site. The result has proved most satisfactory, the engineers reporting a test showing that at least 5,000 gallons of excellent water per hour can be depended upon. The total cost of boring and equipping the well will amount to less than £1,000. A considerable annual expenditure for water will be saved, The length of roadway in which mains have been laid now reaches 22 miles, making about 68 miles of ways, into which upwards of 37 miles of cable have been drawn.

The Corporation has been able to supply electricity to a large number of lamps, pending the construction of the generating station, by connecting the mains to those of the County of London and Brush Provincial Co.'s. This policy was adopted with the view of forming the nucleus of a business, and not in the expectation of earning immediate profit. When the works are opened the lamps of the numerous consumers already connected will at once provide a load for the machines, there being at this date on circuit the equivalent of upwards of 15,000 8 c.p. lamps, with applications in hand for a further 2,500.

The undertaking being in its constructional stage, the accounts are not yet drawn up in Board of Trade form, but a revenue account accompanies the report, the balance of which has been carried into the general balance-sheet.

Richmond (Surrey) Electric Light and Power Co. (Limited).

The report of the directors for the year to Dec. 31 last states that the capital expenditure during the year was £6,452. 12s. 3d., chiefly upon machinery and mains, making a total of £51,246. 4s. The balance to credit of net revenue, including amount brought forward, and after payment of interest charges, &c., is £1,340. 12s. 4d. The directors recommend a dividend on the Ordinary shares at the rate of 4 per cent. (less tax), leaving £129. 3s. 10d. to be carried forward.

The equivalent of 12,352 8 c.p. lamps were connected to the mains at Dec. 31st, an increase equivalent to 2,840 8 c.p. lamps connected for the year. In order to meet the increasing demand for current additional plant has been installed, and further additions will be made during the present year. Considerable extensions have been made to the mains, and further extensions are in contemplation.

BRITISH ELECTRIC TRACTION CO. (LIMITED).—The directors' report for the year ended Dec. 31 states that they have issued 10,000 £10 Six per Cent. Cumulative Preference shares at £12. 10s. per share and £100,000 debenture stock at 116 per cent. The whole of the premiums (amounting to £29,135) have been placed to reserve. Since the closing of the books further issues have been made of 20,000 Preference shares and £100,000 debenture stock, and the proceeds of these issues will be brought into the next account. The subscribed capital is now £300,000, in Ordinary shares of £10 each, £300,000 in Six per Cent. Cumulative Preference shares of £10 each, £200,000 Five per Cent. Perpetual Debenture stock—total, £800,000. The whole of the present authorised share capital of the company having been subscribed, the directors recommend that powers be taken to increase the nominal capital by the creation of 60,000 £10 shares. The gross profits (including £9,804 brought forward), but without taking into account the premiums, amount to £77,999, and, after deducting debenture charges, &c., there remains a net profit of £67,778. It is proposed to write off the remaining preliminary expenses £5,879, reduction of goodwill account £5,000, dividend on Preference shares and a dividend at the rate of 6 per cent. on the Ordinary shares for the year, carrying forward £35,451. Arrangements have been made for the adoption of electric traction in various localities. In some cases agreements have been entered into for the purchase or leasing of existing tramway undertakings, while in others parliamentary powers or orders under the Light Railways Act have been secured or applied for. The total amount expended on works and in negotiations and promotions (after deducting the costs of undertakings which have been sold or transferred, and after writing off expenses incurred in respect of schemes or contracts not proceeded with) is £157,730. The company holds shares and debentures, which cost £420,731, in a large number of existing tramway and similar companies, and in some instances the majority of shares, with a view to the further development of the company's business and the adoption of electric traction. An income of £11,853 has been derived from investments.

BRITISH INSULATED WIRE CO. (LIMITED).—The third ordinary general meeting of the shareholders of this company was held at the works, Prescot, on Wednesday, Mr. W. Marriner Brigg (chairman of the company) presiding. Mr. E. Tracey, the secretary, having read the notice convening the meeting, the Chairman moved the adoption of the report and accounts, and congratulated the shareholders on the substantial progress which the company had made. Orders continued to come in very satisfactorily, and they were now in the position that in the middle of the third month of the year they had sufficient orders in hand to occupy their works for the whole year provided their total output did not exceed that of the past year, though that was not at all likely. They had every reason to look forward to a still more successful future. They

Digitized by Google

had found it desirable to go in for a still further extension of their works and that extension was already commenced. They had also arranged for a quotation of the company's shares on the London and Manchester Stock Exchanges. They had from time to time written off considerable amounts (aggregating some £70,000) against depreciation, and in every way the company was in an excellent position. The motion was unanimously carried, and a further dividend of 10 per cent. on the Ordinary shares (making 15 per cent. for the year) was declared. The retiring directors (Messrs, J. E. Pearson and Thos. Snape) were re-elected and the usual vote of thanks to the chairman terminated the proceedings.

BUENOS AYRES AND BELGRANO ELECTRIC TRAMWAYS CO. (LIMITED).—The directors' report to Dec. 31 states that the total receipts in Buenos Ayres and London amounted to £57,337, and the expenses to £41,391, showing profit on working for 10 months of £15,945. After payment of debenture interest (£9,920), &c., there will remain a sum of £5,927 available, out of which the payment is recommended of a dividend at the rate of 6 per cent. per annum upon the amounts paid on the "A" Preference shares. £2,843 will be carried forward. The transfer of the new concession was made on June 22, 1898, at which time and up to the end of the year a short section, about two miles and a quarter in length, had been worked electrically. This section showed a loss on working to Dec. 31, but this was owing to purely exceptional causes, which have since all been removed. Amongst them, under the agreement with the original concessionaire, the company had to take over a contract for the supply of electric current on onerous conditions. The directors have now entered into a new contract for the supply of current for five years from Jan. 1, 1899, on favourable terms. In December last the company obtained permission from the Buenos Ayres municipality to lay down at once its own double independent track over the whole of the length of the new Belgrano electric lines, an important section of which, connecting Government House (Plaza Mayo) with Palermo Park, has recently been opened with satisfactory results. The company has obtained a concession for a new line, about 1½ miles in length, along Calle Cañitas, forming an alternative and more direct route to Belgrano.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER CO. (LIMITED).—The directors report that the amount available for dividend is £11,506, and the payment is recommended of a dividend of 6 per cent. on the Preference and Ordinary shares, which will absorb £9,900. £1,000 goes to reserve. The company has acquired valuable water rights, which will be used for generating electricity and other purposes. An expert has reported that 500 H.P. can be constantly obtained for eight months of the year, and the directors were further advised that by utilising this power they would be able to generate and accumulate sufficient electricity to work electric and cable systems and do whatever lighting may be required. This would effect a considerable saving, as the steam plant would be shut down for eight months in the year. On the Laxey and Ramsey section there was a profit of £72.

LIVERPOOL DISTRICT LIGHTING CO. LIMITED.—The directors' report for 1898 states that the plant at the Waterloo generating station has been working up to its full output, and it will be necessary to increase the capacity of this station before next winter. The number of lights supplied at the beginning of the year was about 450 ; at Dec. 31 last the equivalent of 2,059 16 c.p. lamps were connected, and orders have been received for over 600 more. The permanent plant at the Gateacre station was connected up at the beginning of the year. The number of lights at the beginning of the year was about 200 which was increased at Dec. 31 to about 1,050. Several orders are in hand and promised for the Gateacre district. In order to meet the necessary expenditure for these additions a further call of £1 per share, which will be due on April 12, has been found necessary. During the year the company has carried out a fairly successful contracting business. A proportion of the general office expenses has been charged against this work, leaving a net profit of £132 from their manufacturing and contracting business. In October last the directors decided to reduce the price for current, in Waterloo, from 8d. to 6d. per unit, and to institute a system of "free" wiring. The number of consumers has increased during the year from 15 to 59, and the company have in hand orders for arc lamps for Great George's-road, Waterloo. This will be a material source of revenue, and generally the directors have no doubt that the balance-sheet for the year 1899 will be a very satisfactory one. As the company have only been working 12 months, and most of that time under very light load, no provision has been made for depreciation.

NORTH STAFFORDSHIRE TRAMWAYS CO.—At a meeting held last week it was announced that the profits, on the half-year's working to Dec. 31 last (after paying debenture interest and the dividend on the Six per Cent. Preference shares), admitted of the payment of a dividend at the rate of 3 per cent. per annum on the Ordinary shares, an appropriation of £1,000 to reserve, and £1,924. 8s. 8d. carried forward. As a result of the agreement for the sale of the undertaking of the North Staffordshire Company the Potteries Electric Traction Co. have purchased the majority of the shares. Mr. Emile Garcke was elected a director of the company, vice Mr. W. J. Carruthers Wain resigned.

OXFORD ELECTRIC CO. (LIMITED).—The ordinary general meeting was held last week. The report stated that the revenue account for 1898 showed a profit (including £18. 17s. 5d. from last year) of £4,692. 9s. 1d After providing £1,613. 13s. 8d. for debenture and other interest and writing off the balance of the capital issue suspense account (£218. 3s. 10d.) and £25. 8s 2d. on account of hire purchase installations, the available balance (£2,835. 3s. 5d.) the directors proposed to appropriate as follows: —£2,500 in payment of a dividend at the rate of 5 per cent. per annum on the share capital, and £250 to be added to the reserve and renewal of plant account, leaving £35. 3s. 5d. to be carried forward. The capital expenditure during the year had been provided for by the issue of Debenture stock. Since the last report the equivalent of 4,564 8 c.p. lamps had been connected to the mains. The increase compared favourably with the progress in 1897, and was partly due to the introduction of the hire purchase system of installing the light. An additional boiler of 200 H.P. capacity had been installed at the works, and the distributing mains extended in various thoroughfares. The capacity of the high-tension mains connecting the generating and sub-stations had been practically doubled during the year, and the efficiency of the system thereby considerably increased. The control of the distribution of current had been transferred from Broad-street to the generating station at Osney with satisfactory results. The report and accounts were adopted.

SMITHFIELD MARKETS ELECTRIC SUPPLY CO. (LIMITED).—An extraordinary meeting was held on Friday, Mr. J. Browne Martin presiding, to pass resolutions for making alterations in the articles of association, so as to bring them into conformity with the requirements of the Committee of the Stock Exchange. The resolutions were duly approved. The Chairman said that the business of the company was progressing in a satisfactory manner. The first issue of shares was nearly doubly subscribed for. There was no intention of issuing the second part of the capital immediately. Mr. Ernest Schenk said he had been furnished with a statement which showed that their cost of production was actually lower than a great many other companies whose production of current was greater. All that was said at the last meeting as to their business being on the increase had been verified. Since Sept. 30 they had—connected and on order—increased their business by about 1,000 8 c.p. lamps. Several of their old customers had come back. The board had applied for powers to extend their operations in the city, and they had secured 8,000 signatures to a petition in support of their application.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (since Feb. 2, 1899). Price of silver 27½d. per oz. (March 16). Consols (2¾ per cent.) 110¼—110½ for money, 110½—110¾ for account ; 2½ per cent. 103⅜—103⅝ (March 16), Stock Exchange Settling Days : Consols, April 6 ; Stocks and Shares Continuation Days, March 27 and April 11 ; Ticket Days, March 28 and April 12 ; Pay Days, March 29 and April 13 ; Mining Share Carry over Days, March 25 and April 10.

ARON ELECTRICITY METER (LIMITED).—The transfer books of the 6 per cent. Cumulative Preference shares of this company will be closed from March 23 to April 1 inclusive, preparatory to the issue of interim dividend warrants.

BUDAPESTE ALLGEMEINE ELECTRIZITATS-ACTIENGESELLSCHAFT.—The report of this company for the year 1898 states that the undertaking has made considerable progress, there being at the end of the year an equivalent of 84,793 16 c.p. lamps connected against 73,682 in 1897. Various extensions of the mains were made and the profits amounted to 191,714.07 kroner. After carrying various sums to reserve and renewal accounts, payment of debenture interest, &c., a dividend of 5 per cent. has been declared, against 4 per cent. for the previous year. Much of the credit for this satisfactory state of affairs is due to the commercial and technical director (Mr. E. de Fodor), who was, after having been technical director only for some time, appointed to the former post early in the year.

CITY AND SOUTH LONDON RAILWAY CO.—Letters of allotment for the recent issue of £375,000 Ordinary share capital of this company were posted on Wednesday.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING CO. (LIMITED).—The transfer books and register of members will be closed from the 14th to the 27th inst. inclusive, preparatory to the payment of the Preference share dividend. The directors recommend the payment of the dividend on the Six per Cent. Preference shares for the six months to Dec. 31, carrying forward £5,774.

EASTERN TELEGRAPH CO. (LIMITED).—Payment will be made on April 14 of dividends, at the rate of 3½ per cent. per annum (less tax), on the Preference stock of this company for the quarter ending March 31, 1899, and an interim dividend of 1¼ per cent. on the Ordinary stock (free of tax), in respect of profits for the quarter ended Dec. 31, 1898. The transfer books will be closed from April 7 to 14, inclusive.

F. H. ROYCE AND CO. (LIMITED).—During the week this company, which has an authorised share capital of £60,500, invited applications for 6,000 Six per Cent. Cumulative Preference shares of £5 each.

GERMAN-ATLANTIC TELEGRAPH CO. (LIMITED), COLOGNE-ON-RHINE.—As various inaccurate statements concerning the projected German-Atlantic cable have been published, we have been asked to insert the following particulars :—"The firm of Felten and Guilleaume, of Mulheim-on-Rhine, some time ago obtained from the German Postal Administration a concession for establishing direct cable communication from the North German coast *viâ* the Azores to the United States of North America. This concession secures to the undertaking a certain amount of traffic revenue from Germany, and also arrangements have been made with American telegraph companies whereby American traffic to Germany will be transmitted over the new German cable. For the purpose of floating a joint stock company with the above mentioned title, with a capital of 20,000,000 marks, to carry out this concession and to enter into certain contracts made in connection with same, a syndicate, under the leadership of the A. Schaafdhausen'schen

Digitized by Google

Bankverein, of Cologne, has been formed by the following firms: Felten and Guilleaume, Mulheim-on-Rhine, Disconto-Gesellschaft, Dresdner Bank, Darmstadter Bank, S. Bleichroder, Born and Busse, of Berlin, Sal. Oppenheim, jr., & Co., and Levy, of Cologne. Within this group arrangements have been made to carry out, conjointly by the German-Atlantic Telegraph Co. and the firm of Felten and Guilleaume, the erection at Nordenham, on the North German seacoast, of a submarine cable factory, for which the requisite territory has been taken over (from another German firm who had destined it for the same purpose). The new company will be formed under the style of 'Deutsche See-Kabelwerke Actiengeselschaft,' with the domicile at Cologne, and a capital of 2,000,000 to 3,000,000 marks. This company is also said to undertake the laying and repairing of cables and will procure a cable ship for this purpose. Although the floating of the above company is assured there are still some formalities to go through which, no doubt, will be shortly completed. The whole of the capital for the company which has obtained the concession has been subscribed.

GESELLSCHAFT FÜR ELEKTRISCHE UNTERNEHMUNGEN (BERLIN).—A dividend of 10 per cent. for 1898, compared with 8½ per cent. for 1897, has been declared.

WILLIAM JAMES GLOVER AND CO. (established 1818) (LIMITED).—On another page will be found the abridged prospectus of this company, which is formed with a share capital of £100,000 in 5 per cent. Cumulative Preference shares and Ordinary shares of £1 each. Applications are now invited for 40,000 Preference shares and 10,000 Ordinary shares at par, payable 2s. 6d. on application, and 7s. 6d. on allotment, the balance by instalments of 5s. each at intervals. It will be seen that the company has been established over 80 years in connection with wire rope manufacture, and the prospectus states that the company will combine three manufactures: wire drawing, rubber and insulating material, and electric cables. The old-established works at St. Helens have been secured, and particulars regarding these and other properties taken over will be found set out. The services of Mr. Heyl-Dia have been secured, and he joins the board as managing director. Certificates are set out from Messrs. Banner, Spencer and Co., chartered accountants, who have examined the books of the old company for some years past, and the works have been valued by Messrs. Rushton, Son and Kenyon, of Manchester. The lists open to-morrow (Saturday) and close on Wednesday.

"MOTOR" AKTIENGESELLSCHAFT FUR ANGEWANDTE ELEKTRICITAT (BADEN).—A dividend of 6 per cent. has been declared for the past year, against 5 per cent. in 1897.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE CO. (LIMITED).—The directors report that for the year 1898 the electrical operations show a profit of £236. 2s. The directors are considering the advisability of an extension of plant in both sections (gas and electric lighting) rendered necessary by increase of business. An Order in Council under the Electric Light and Power Act, 1896, has at length received the sanction of the Governor in Council for the full term of 42 years. The company's position in connection with the supply of electricity for Rockhampton and its suburbs being thus assured, the directors have decided upon issuing debentures on the London market.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has been asked to appoint a special settling day in 5,530 £5 (fully paid) vendors' Six per Cent. Cumulative Preference shares (Nos. 1 to 5,530), and a further issue of 7,500 £5 (fully paid) Six per Cent. Cumulative Preference shares (Nos. 20,001 to 27,500) of the *British Insulated Wire Co. (Limited)*, and to allow 24,000 £5 (fully paid) Ordinary shares (Nos. 10,001 to 34,000) of the *New General Traction Co.* to be quoted in official list.

TELEGRAPH MANUFACTURING CO. (LIMITED.)—The Preference share transfer books of this company will be closed from the 16th to the 30th inst., inclusive.

WILLANS AND ROBINSON (LIMITED.)—The transfer registers will be closed, prior to the ordinary general meeting, from 15th to 29th inst. inclusive.

NOTES.

THE report relating to telephone service in foreign countries, which have just been laid before Parliament, and a summary of which will be found in our columns this week, may be studied with profit by everybody interested in the welfare and future control of the telephone in this country. One thing made clear by a very casual study of the figures now available is, that the statistics hitherto quoted have been studiously selected for the special purpose of attacking the English system. Taking all things into consideration, that system comes out very well by comparison with the systems of which we now have trustworthy information. The tariffs, varying as they do in various countries, and even in the same country, point to the conclusion that they are determined by local circumstances, such as the size of area, the character of the place, whether commercial or residential; and especially the rate of wages and the general cost of installations.

NOWHERE do high profits appear to be made; and Amsterdam and Rotterdam, the sole instances of municipal management, are not encouraging for similar experiments here, if the payment of interest on capital outlay and reserves for depreciation are—as they always ought to be—taken into account. Nor when the facts are carefully studied is the much talked of superiority of Sweden and Norway so real as it seems to be. There are at least three systems in Stockholm alone; but it is pretty plain that the Government are awakening to the desirability of unification; and we can hardly suppose that the public is not of the same mind. The toll system, pure and simple, seems to find an exponent in Switzerland only—a country so different in every respect from our own that we entertain some misgivings as to adopting a system certain to prove an unmitigated nuisance to the business man

A HOWL of indignant protest has been raised against the Bill in Parliament of the Baker-street and Waterloo Railway Co., renamed the Waterloo, Euston and Paddington Railway Co. The Bill provides for the construction of a power station and terminal yard in what the opponents admiringly describe as "the most picturesque part of Paddington." True, the description may puzzle the minds of some as to the exact locality referred to; yet, nevertheless, we can appreciate to some extent the desire of the residents not to be thus singled out, while there are less "picturesque" parts that might be so favoured. In the early days of railroading many a short-sighted borough voted railways a nuisance, and had the stations erected as far away as possible. To-day those boroughs are in the rear of commerce, in consequence. As to the proximity of a steam-driven power station to any "picturesque part," we have always deprecated following this course wherever it is practicable to erect the works in a locality less liable to be injured by tall chimneys, smoke and machinery. Polyphase transmission renders this easy in the case of electrical undertakings of the class to which the railway in question belongs; and our advice to the company is to stick out for its terminal yard, but to erect its power station in a less "picturesque part of Paddington," or even still further away.

PADDINGTON may interest but little the majority of our readers, but the application of polyphase currents to railway working appeals to a much wider circle. It is a subject which was brought prominently forward on Wednesday evening last, at the Society of Arts, during the discussion on Mr. PHILIP DAWSON'S paper on electric traction, a reprint of which we commence this week. One or two speakers expressed the view that the success of the Jungfrau and Gorner Grat railways pointed to the advisability of adopting polyphase working throughout on electric railways. If that argument be advanced, what does the success of the Chicago and the Liverpool electric railways point to, since these are much older and much larger systems of railways? Considering that the Gorner Grat line was only opened in December, 1897, and the Jungfrau line late last summer, there is considerable force in Mr. DAWSON'S reply that he adheres to continuous current motors because he knows what they can be relied upon to do, and can get guarantees, whereas there appears to be great difficulty in getting equally good guarantees for polyphase motors.

Digitized by Google

Mr. Mordey directed attention to a very practical and common sense way out of the difficulty viz., that in large traction schemes polyphase generators should be adopted for the power station, the power being transformed at sub-stations to continuous current. This would pave the way for the ultimate adoption of polyphase traction, should such be sufficiently perfected, and it would minimise the cost of converting from one system to the other. Although this has not been the principal object in view, the practice recommended by Mr. Mordey has been adopted already on several lines, as, for example, at Dublin, and has proved quite successful.

Conduit systems came in for some commendation from Mr. Kilburn Scott, who, unintentionally as it subsequently appeared, gave some colour to the idea which has been circulated by a misinformed newspaper press, that the trolley system is extensively and rapidly being superseded by the conduit system on American tramways. A greater error never gained currency; but inasmuch as a false rumour once started is difficult to overtake, we have found it a troublesome task to disabuse the minds of local authorities of the idea that they ought to oppose the trolley system because it is already being supplanted by something better. Much injustice to the claims of the trolley system has arisen from the circulation of this preposterous notion. Thousands of miles of trolley line are working in America with complete success, financially as well as from an engineering point of view; and the proprietors of these lines would be the first to ridicule the suggestion that a conduit system would be in any sense an improvement.

Undoubtedly the conduit system, as perfected by long experience in Washington, and recently adopted in New York, possesses characteristics which, in certain special circumstances, make it preferable to the overhead trolley system. We are of the opinion, however, that the traction system, whether conduit or surface contact or otherwise, has yet to be developed which will be found superior to the trolley system for the general purpose of town tramways or interurban light railways. This being so, it is obviously prudent to adopt the trolley system for the present, rather than to spend large sums of money in laying down an expensive conduit system that may be rendered obsolete in a few years.

However much biology and electrical science may have advanced independently during the present decade, a satisfactory explanation of the peculiar properties possessed by the queer electric fish is still wanting. The *malapterurus* of the Nile, which was the subject of a lecture by Prof. Gotch at the Royal Institution last Friday evening, is a most superior sort of electrical fish, for, unlike the *gymnotus* and the *torpedo*, its electric organ does not impede its motion, and even appears, according to the lecturer, to whet its intelligence. A comparison of the *malapterurus* with other fish of a like nature has induced Prof. Gotch to discredit the older theories of the method by which these animals generate electricity, and to incline to the view that the seat of the electromotive force is the nerve centre itself and not the collection of "plates" hitherto considered to be the electric organ; he does not, however, indicate the precise function of these "plates." These latter are formed of a modified muscular substance and number about two millions. They are separated by an albuminous composition and each is connected by a single nerve fibre to the nerve centre. The E.M.F. of each of these cells, measured, with the help of Mr. G. J. Burch, by means of a capillary electrometer, is about 0·04 or 0·05 volt, *i.e.*, of the same order as the E.M.F. generated by the contraction of a muscle. The time lag between the excitation of the nerve and the maximum E.M.F., proved to be about $\frac{1}{1000}$th of a second, and a single momentary excitation of the nerve suffices to generate an oscillatory E.M.F. Prof. Gotch's hypothesis might possibly be completed and rendered more probable by assuming that the collection of "plates" is nothing more or less than a condenser, or rather a series of condensers, charged at will by the fish; and this would account both for the time-lag and the oscillatory discharge.

The capillary electrometer experiments could not, of course, be repeated at the lecture, but two live *malapteruri*, kindly lent by the Liverpool Corporation, were on view, and currents generated by them were demonstrated audibly and optically by means of a telephone and a prepared frog-nerve respectively, although part of the current was necessarily shunted through the hand of the intrepid lecturer. After the discourse, the audience were invited to test for themselves the "shocking" propensities of the animals. In this the fish again showed evidence of their intelligence, for when teased by the sterner sex fatigue very soon set in, but in response to the more delicate touch of the ladies, they were almost invariably more accommodating.

The Willans engine has been so closely identified with the development of electric supply stations in this country that more than ordinary interest attaches to the tenth half-yearly report of the directors of Messrs. Willans and Robinson (Limited), which has just been issued. Particulars of the report will be found in another column, from which it will be seen that the Company is in a very flourishing condition. Among many other indications of prosperity we may note that the sums reserved out of profits in the five years since the Company was formed aggregate £38,852, a figure which exceeds the amount paid for the goodwill of the business. New works are about to be erected near Chester for the boiler-making departments: and, at the Rugby works, the largest stock size of Willans engine will probably very shortly be increased, the present largest stock size—1,500 h.p.—having proved very popular.

We have received a copy of the first number of *Electrical World and Electrical Engineer*, our new American contemporary, which has been evolved out of a coalescence of the two leading electrical journals in the United States. The new publication appears to combine the good qualities of its progenitors, and to have eliminated what in them may have been of inferior merit. We repeat our good wishes for its success.

Cable Interruptions and Repairs.—

	Date of Interruption.	Date of Repair.
Dakar—Bathurst	Feb. 9, 1899 ...	Mar. 15, 1899
Paramaribo—Cayenne	Feb. 10, 1899 ...	—
Cayenne—Pinheiro	Mar. 10, 1899 ...	—

New International Telephone Trunk Line.—Telephonic communication can now be held between Berlin and Arnheim, in Holland. The cost of a three minutes' conversation is three marks.

The Wireless Telegraph to France.—We hear that the French station for the cross-channel wireless telegraph trials will not be at Boulogne itself, but at Wimereux, a village two miles to the west of Boulogne, the English station being at South Foreland. The distance between the two stations will thus be 30 miles.

Electrocution.—The electrocution of a female criminal at New York on Monday last, has once more directed attention forcibly to the unnecessary cruelties attendant upon this barbarous method of carrying out the death sentence. Apart from the mental torture, due to the elaborate preparations, while adjusting the criminal to the electrical chair, the fact that it was considered necessary to maintain the fatal shock for 60 seconds should be sufficient to condemn the practice. In the latest case, it appears, 8 amperes at 1,760 volts were maintained for 4 seconds, followed by 2 amperes at 200 volts; in other words, no less than 18 H.P. was expended upon the body of the wretched criminal.

Obituary.—We regret to announce the death, in Schenectady, of Mr. John Kruesi, the chief mechanical engineer of the General Electric Co. of America. Mr. Kruesi was born in Sperchер, Switzerland, in 1843, and remained in his own country until 1867, when he proceeded to Paris. On the outbreak of the Franco-Prussian war he came over to London and went thence to the United States. Shortly after his arrival in the latter country he was engaged by Mr. T. A. Edison. He was associated with the great inventor in evolving the tinfoil phonograph, and in the early electric lighting work in New York City. When the Edison Machine Works were formed Mr. Kruesi was appointed assistant general manager, and when they were moved to Schenectady he was mainly responsible for the design and erection of the works there. Mr. Kruesi died from an attack of influenza after only three or four days' illness.

Telephone Rates in New York.—A bill for the regulation of telephone charges in the State of New York, drawn up by the committee appointed for that purpose by the New York Board of Trade and Transportation, was recently introduced simultaneously in the Senate and the Assembly. The bill provides that the telephone rates in cities of 1,000,000 inhabitants and over shall not exceed $125 a year; in cities of 500,000 to 1,000,000 not to exceed $85; in those of 100,000 to 500,000 not to exceed $48; those of 20,000 to 100,000 not to exceed $36; from 8,000 to 20,000 not over $30, and in all places having less than 8,000 inhabitants not to exceed $27 a year. The charge for local messages at public or pay stations is fixed not to exceed 10c. for the first five minutes, and 5c. for each additional five minutes. The provision is made, however, that the annual rates named in the bill may be raised if it shall be made to appear to the satisfaction of the State officers in charge of the matter that the telephone company is not making, in addition to the amount paid for interest on bonded indebtedness, a net profit of 10 per cent. upon all cash capital. The rate may, however, be lowered if it appear that the company is making a profit of more than 10 per cent.

Cape to Cairo Telegraph Scheme.—Her von Bülow, the German Foreign Secretary, made the following statement in the Reichstag, on Tuesday last, concerning Mr. Cecil Rhodes's scheme for a trans-African Cape to Cairo telegraph:—

With regard to the negotiations which have been conducted here during the last few days between those German departments of State which are concerned and Mr. Cecil Rhodes, I cannot yet give all the details, and I must also take into account the fact that these negotiations are still pending; but I should like to give such information as I can without prejudicing the interests involved. An agreement has been effected between the Trans-African Telegraph Co. and the German Government concerning the construction of a line of telegraph from South to North through German East African territory in connection with the existing South African line. When this agreement will be published, and when it will come into force, depends upon the future progress of other negotiations. I can already say, however, that by the terms of this agreement our rights and our interests are safeguarded in every respect. The Trans-African Telegraph Co. receives permission to construct the line in question across German territory at its own cost. The work must be completed within five years at the outside, and all officials and workmen of the Company will be subject during their stay in our territory to German law, and must obey the orders of the German Governor. The Company is under an obligation to erect at its own expense a further line joining the two stations, in Rhodesia on the one side and in British East Africa on the other, which are nearest to the German frontiers. This line will be destined for the telegraphic service of German East Africa, and will be the property of the German Government. The cost of maintaining this line will be borne by the German Government, which has the right to construct additional lines at its own cost. These telegraph lines belonging to the German Government will be maintained at the Company's expense. The Government reserves to itself the exclusive right of establishing and working telegraph stations in its territory, and at the end of 40 years it may take possession of the lines without payment.

Annual Dinner of the Northern Society of Electrical Engineers.—At the sixth annual dinner of this Society which was held in Manchester, Mr. Ferranti, the new President, responding to the toast of the evening, which was proposed by Mr. Henry Edmunds, referred to the progress of the electrical industry in this country within recent years. The fact that towns are well supplied with gas had, he said, been against the general introduction of public electric lighting in the past; but we could now congratulate ourselves that we were in a satisfactory condition of forwardness instead of being behind other nations. In electric traction, however, it was not because we had been too well served that we had not gone ahead, but because legislation had deterred people from investing in such undertakings. One of the most serious things that affected the industry was the great disadvantage that sprang from the evils of socialism, and municipalities were more and more supplying ratepayers with everything they desired. In electric lighting work they claimed to be successful, but how was it possible to fail with such an excellent business when it was a monopoly? Municipal trading in its worst form was the next step, for the municipalities were now proposing to sell, not merely gas, water and electricity, but to manufacture the articles essential to such undertakings. He was glad there was a strong feeling against that most pernicious form of socialism. Another very objectionable feature of municipal action was the practice of inserting special labour clauses in contracts to regulate the hours of labour, the rate of charges, and the methods in which masters should deal with their men and conduct their business generally. By heeding the demands of the trades unions the municipal representatives were simply buying votes by the use of public money. How were English manufacturers to compete with foreign countries if they were subject to such conditions? We were free traders, but we ought to have free trade in our own country, and engineers should not be fettered and forced to raise artificially the price of the work they performed. Mr. Ferranti's speech was received with great enthusiasm.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, March 24th.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Papers to be read: (1) "On the Criterion for the Oscillatory Discharge of a Condenser," by Dr. Barton and Prof. Morton; (2) "The Minor Variations of the Clark Cell," by A. P. Trotter.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Transparency and Opacity," by the Right Hon. Lord Rayleigh, F.R.S.

SATURDAY, March 25th.

INSTITUTION OF JUNIOR ENGINEERS.

3 p.m. Visit to the Testing Station of the British Fire Prevention Committee at Hanover Gate, Regent's Park, London.

NORTH EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7 p.m. General Meeting of the Graduate Section in the Institution Lecture Hall, 4, St. Nicholas-buildings West, Newcastle-on-Tyne. Paper to be read: "The Application of Electricity to Coal Mining," by T. Duckitt.

TUESDAY, March 28th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be submitted for discussion: "Alloys of Iron and Nickel," by R. A. Hadfield.

THE TELEPHONE SERVICE IN FOREIGN COUNTRIES.

A parliamentary paper* just issued, containing "Reports respecting the Telephone Service in various Foreign Countries," is most interesting and opportune at the present juncture when the Government are contemplating important changes in the Telephone organisation of this country. These reports originated with a request made to the Foreign Office by Mr. A. D. Provand, M.P. for Blackfriars, Glasgow, that information should be obtained by British Consuls in the various cities of Europe and the United States under headings categorically enumerated in a memorandum dated December 20, 1897. The questions, 23 in number, may be summarised as follows: Those relating to population and size of area; nature of concession whether private, State or municipal; its powers and rights of wayleaves; numbers of subscribers; tariffs and hours of service; wages of workmen and operators, with their hours of attendance. To these were added questions as to the composition of the wires, the character of the circuits; and where the plant, including apparatus, was manufactured, It was also desired that copies of accounts should be obtained with details of capital expended, and profits or dividends earned; but we may state at once that the answers on these points are either not forthcoming, or in the majority of cases, too ambiguous to be of any value. The same may be said of answers to question (18)—"Quality of service, and whether the subscribers are generally satisfied"?—which when answered at all, being with one exception in the affirmative, is suggestive of diplomacy rather than judicial accuracy. The exception confirms this impression, the Consul at Ghent reporting that the public are satisfied with the working, "but complain that 200fr. per subscription is too high." As to what we should call the general efficiency of the service the reports are silent—a fact the more remarkable seeing that a large proportion of the circuits are single wired, and some of them worked entirely by private companies on business principles. As regards the wires the uniform answer is silicum or phospher bronze; single as a rule for overhead, double and of copper for underground. The plant and appliances appear to have been obtained mostly from Stockholm and Germany; England which had a good share in the manufacture at one time being now, we are told, shut out of the market. Answers to the other and more important questions will appear as we examine the reports in detail.

The ground covered by these consular Papers embraces all the industrial countries of the Continent, and furnishes detailed information as to the chief cities of Austria-Hungary, Bavaria, Germany, Italy, the Netherlands, Belgium, Sweden and Norway, and of Switzerland. Of the French telephone service no useful particulars were obtainable; and from Russia only one example is furnished, that of Helsingfors. From the United States also only one report has been received, which, however, is a very striking document in several respects, emanating as it does from the Telephone Company of New York, and disclosing a condition of affairs in marked contrast with what is reported from the cities of Europe. This being so it will be convenient to speak of it at the outset, although the report comes last in the series, and is very brief.

The New York Telephone Co. is the lineal successor of the Bell Telephone Co., which commenced operations in 1878, and was absorbed by the Metropolitan Co. in 1880, being in turn absorbed by the present Company about three years ago. The area covered is about 62½ square miles, with a population of 1,500,000. The Company is organised under the State law, enjoying many privileges as regards wayleaves, &c., and possesses a practical monopoly, but without exclusive rights. Consul-General Sanderson, in his memorandum accompanying the inclosure, speaks of the "satisfactory nature" of the existing service, but also of the efforts made to compel the Company to reduce its charges. He says nothing, however, of municipal corruption defeating these efforts, as suggested by Mr. Provand in our columns last week; nor do we see how the municipalities of this country would escape similar insinuations, with just as much foundation, if the local authorities ever have the same motive for protecting themselves against outside competition. The published tariff of the Company is given as follows:—

90 dollars for	600 messages, say	.....	.....	£18
120 „	1,000 „	„	... .	24
145 „	1,500 „	„	....	29

In the report itself the charges are said "to vary from £15. 10s. to £49 10s. per annum, regulated by the amount of service rendered." "The company, up to July 1, 1896, paid no dividend, the profits being devoted to extending and improving, their property; since that time they have paid dividends at the rate of 6 per cent. per annum." It is not stated how long these charges have prevailed, or whether they have changed for better or worse; but it is a notable fact that since 1895 the subscribers have increased at the rate of three to four thousand each year, whereas for the preceding five or six years the numbers increased very slowly. The figures from 1890 are given below:—

July 1, 1890	8,224	July 1, 1895	10,396
„ 1891	8,527	„ 1896	13,337
„ 1892	8,736	„ 1897	16,786
„ 1893	9,013	Dec. 1, 1897	20,937
„ 1894	9,914		

We give also in full the statement of the Company as to the wages paid to their workmen and operators. It will be seen further on that these rates are double and even treble those paid in many European countries to the same class of employés:—

"The wages paid to workmen range from $9 (about 37s.) to $28 (about £5. 15s.) per week. As a rule they are not required to work on holidays or Sundays, but they must report for duty, and if their services are required they are paid overtime, generally at the rate of about one and a-half. When ill they receive their wages for what is considered a reasonable time depending on the nature of the case, and the Company maintain a policy of insurance to cover the employer's liability in cases of accident or death. In cases where the employer cannot properly be held liable it is the rule, rather than the exception, to grant some compensation. The wages paid to workwomen range from $3 (about 12s. 4d.) to $17 (about £3. 10s.) a week."

Turning now to the Continent of Europe, Italy is the principal country at all resembling New York, if we may judge from the reports on the service in the cities of Rome and Florence. Both places are served by private companies, which are the survivors of other companies now defunct or amalgamated, and which hold concessions from the Italian Government for 25 years, commencing on January 1, 1898. These concessions are, however, subject to cancellation after 12 years on payment, as compensation, of a sum equal to the average net profit of the three preceding years, multiplied by the number of years which each concession has still to run. If undisturbed for the full 25 years, the plant, lines and offices become the property of the State. A tax of 10 per cent. is imposed on the gross profits of each concession, free communication with postal and telegraph offices, and a reduction of 50 per cent. in favour of all Government, provincial or municipal offices. On the other hand, the companies possess almost arbitrary powers in respect of wayleaves. In Rome and vicinity the concession covers an area including a population of about 500,000. The subscription is 168 lire (£6. 14s.) annually, with an extra charge for distances exceeding three kilometres. The service is continuous, night and day. Subscribers number 2,102. About 50 women are employed at the Central Bureau working seven to eight hours a day with wages of 25s. to 40s. per month. Workmen's wages are set down at 1s. 8d. to 3s. 4d. a day, working ten hours. The dividends of the Company which were formerly 3 per cent. are now, under the more secure conditions, 6 per cent. In Florence the same rate of wages prevails, and there is the same continuous service all night and all Sundays. A fortnight's leave of absence is granted annually to the operators, and a holiday on each alternate Sunday. The subscription ranges from £6. 10s. within 1 kilo. to £9. 3s. 4d. within 3 kilos. There are about 900 subscribers in a population of 250,000. Although the law requires double wires, it has not yet been generally enforced, and single wires are the rule. As regards dividends the concluding words of the Florence report are worth quoting; they apply no doubt as well to Rome and other Italian cities:—

"The old local Company distributed yearly a dividend varying from 2 to 3 per cent.; the new Company which has absorbed the others has not

* Commercial, No. 1 (1899).

Digitized by Google

yet published a balance-sheet, and it is expected that the dividend, if any, will not be in excess to the above-mentioned. With 10 per cent. concession tax, and 20 per cent. income tax, and the necessity of refunding the capital, a very little extra profit can be available for distribution."

Helsingfors, in Russia, is the only other instance reported upon where the telephone service is in the exclusive control of a private company. The same story comes from there as from Italy, several competing companies, ending in amalgamation and a joint concession. In the case of Helsingfors, with only 80,000 inhabitants, the Company obtained its privileges from the municipality on very easy terms, paying only one mark for every wire in the town; but nothing for its 16 trunk wires along the roads. It has 2,800 subscribers. The subscription is from £5 to £5. 10s. per annum, if the instrument and line are hired, and £3. 10s. if they are bought. Workmen and female operators receive on an average 3s. for a day of 10 hours. No information is afforded as to the profits of the undertaking, nor as to the service of any other town in Russia.

Of municipal telephony the only examples forthcoming are from the Netherlands, Amsterdam and Rotterdam having taken over in 1896 the systems previously worked by private companies, and extending in both places to a radius of $3\frac{1}{8}$ English miles. The concession to the municipalities is granted by the State for a period of 25 years, with option of purchase at any earlier period. Full powers are granted in respect of wayleaves, except as touching property of the Government. The system is double wired, and is a combination of overhead and underground. Amsterdam has a population of 500,000, with subscribers numbering 1,925; Rotterdam a population of 295,000, and 1,320 subscribers. In Amsterdam, each subscriber pays £2. 1s. 8d. entrance fee, and £7. 10s. per annum. In Rotterdam the entrance fee is rather less, and for private (not business) subscribers, the rate is £5. 10s. The service is continuous night and day. No royalty is paid to the State, the only consideration imposed being the obligation to provide all cable wires for connecting subscribers with telegraph offices and trunk lines—both in the hands of the State. The capital outlay is estimated for each connection at £33. 6s. 8d. in Amsterdam, and £45 in Rotterdam. For the first-named place the receipts and expenditure in 1897 have been published, and will be read with interest. The surplus in that year was £3,987. 1s. 8d., expenditure being £10,416. 13s. 4d., against receipts £14,403. 15s. A surplus of over £4,000 was estimated for 1898. In Rotterdam the estimate for that year is given as £5,567—interest and redemption of the capital outlay of £64,667 to be defrayed from that amount. The wages in Amsterdam, which appear to be lower than in Rotterdam, are, for skilled workmen 23s., labourers 20s.; working hours, 7 a.m. to 7 p.m. Girl operators are taken on at 5s. a week, rising to a maximum of 16s. 8d. a week, working seven hours a day, Sunday and night-work (every seventh week) included. Pension for old age or when injured during service, and compensation to relatives if killed, are fixed by the Rotterdam Municipal Council according to years of service and rate of wages.

We now turn from these solitary instances of municipal control to cases of mixed services—partly governmental, partly private enterprise—which are afforded by the much talked-of systems of Sweden and Norway. Beginning with private associations connecting small towns and villages merely for mutual convenience, telephony had a good start in the country districts before the dividend-paying concerns were developed in such places as Stockholm; and still more of the Government system, which did not come into operation until 1891. In that city the Bell Company started in 1880, the Allmänna Company three years later; and both companies, under a national concession, have exercised powers of wayleave greater, probably, than any obtained elsewhere. The competition of the Government, commenced in 1891, resulted in the two systems being connected and the double wire being adopted throughout Stockholm. With a population of 271,638, the Stockholm subscribers number 19,369, of which 12,899 belong to the Allmänna Company, 4,506 to the State service, and 1,964 to the Bell Company. It is not clear, however, whether these figures represent separate subscribers, or whether any of them subscribe to more than one system. The tariff of the State telephone department only is quoted; but it is presumed that the three competitors' charges are alike—viz., an entrance fee of £2. 15s. 6d., and a similar amount per annum for ordinary business purposes, but £4. 8s. 10d. per annum if with the right of an unlimited number of calls. Some reduction is made for limited service, and a private telephone may be had for £2 a year, with an entrance fee of 11s. 1d. The average length of wire within the Stockholm area is given as 1·3 kilo., and the approximate capital outlay per wire estimated at £2. 15s. 6d.; but there is certainly some misunderstanding here, the cost in other places being estimated immensely higher. The State appears to be earning no profit itself, but is threatening with reduced dividends its competitors, one of which (the Allmänna) used to pay 8 per cent. to its shareholders. Wages in Stockholm are 2s. 9d. to 4s. 1d. per 10 hours' day. No holidays except Sundays. For the workwomen employed in the exchanges the pay is 50s. a month. They get one Sunday out of three for a holiday; extra pay for night work. From this we gather that the service is continuous. It is incidentally mentioned that the average cost of a telegram in Sweden and Norway is $9\frac{1}{2}$d.—about 2d. higher than in this country; and this affords an explanation of Government interposition, the State telegraphs having suffered severely by the competition of the telephone companies. Similar reasons, no doubt, operated in the case of Austria-Hungary, where the State allowed the companies a free hand until 1893-5.

According to the account received of the Christiania Telephone Co., wages paid by them in that city are even lower than in Stockholm. Rates of subscription for single lines, not exceeding 1,500 metres, connected with the central station, £4. 8s. 10d. per year; for each additional 500 metres, 8s. 3d. Extra charges are made for calls in excess of 6,000 a year, and guarantees are required for at least three years' subscription if a new line is required 500 metres from the nearest central station. Christiania has a population of 200,000, of whom 6,475 are subscribers to the Company's system. Last year's dividend was $5\frac{1}{2}$ per cent.

From Bergen, a town of 65,000 to 70,000 inhabitants, there is a similar report of the Joint Stock Company's operations, with 1,800 subscribers, and earning apparently the same amount of dividend on capital outlay. But the vice-consul's English is not always perfect, and we quote with confidence only one of his statements: (18) "The service, exclusively ladies, can be said to be generally satisfactory." It should be noted lastly that for these, several private undertakings in Sweden and Norway, no royalties have to be paid to either the State or the municipality, the latter only claiming special rates for its own service.

There remain to be considered only the purely State telephone systems. Of these, the German and Bavarian have been in Government hands from the first; the Swiss also, except for a private venture at Zurich, which was speedily absorbed into the Federal system. In Austria-Hungary, as well as in Belgium, the acquisition of the telephones was postponed until 1893 or thereabouts, the local undertakings until then being in private hands, although the trunk wires as well as the telegraphs were in most instances owned by the State.

In Vienna and Trieste the companies' systems were taken over by the Government for a consideration, the amount of which is not stated; but for the connections in Prague "and everything appertaining thereto," the sum of 1,000,000fl. was paid by the Imperial Government. The Vienna system extends over an area of 69 square miles, 70 per cent. of the wires being double, the remaining 30 per cent. single. The population numbers 1,400,000. At the time of the transfer there were 7,700 subscribers, which in 1897 had increased to 10,573. Within a radius of $1\frac{1}{4}$ miles from the central exchanges the subscription is £8. 6s. 8d. per annum. At these central exchanges, the service is continuous throughout the day and night. The female attendants are paid from 50s. to 70s. a month; labourers 2s. to 3s. a day. Trieste, with 163,979 inhabitants, has 1,020 subscribers. Capital outlay per wire is estimated at about £17. 10s., the average length being

* Connection by double wire increases by 50 per cent. the subscription tariff of the first ordinary station and line, but such increase may not exceed 100fr. for the first three kilometres.

† Reduction of 50fr. off the subscription tariff for each connection applied for after the first.

‡ Reduction of 50fr. for each connection not exceeding 1,500 metres in a straight line from the central office.

§ Reduction of 10 per cent. off the subscription tariff for each connection applied for after the first.

Half-yearly Subscriptions.—Half-yearly subscribers pay three-fifths of the above-mentioned tariffs, except in the Charleroy group, where the subscription is 120fr. within the radius of three kilometres. The subscriber is bound for three half-yearly terms during three consecutive years.

1,255 metres. The general circumstances are the same as in Vienna. Prague has a population of 320,805, the subscribers to telephone exchanges numbering 2,200. The initial tax is 50fl. for the first 500 metres, and an annual subscription of 50fl. Wages are about the same as in Vienna. In the Prague report mention is made of "telegrams destined for subscribers on the Exchange are telephoned to them"; also that subscribers may telephone their telegrams to the post office for transmission by telegraph.

In Belgium the concessions to private companies expired in 1893, when the telephone systems came under Government control. Such, at least, was the case at Ghent, for which alone particulars on this point are given in the report. Ghent, with its surrounding districts, has a population of 200,000. The subscribers number 900, but whether this is in Ghent proper is not quite clear. Some tabulated particulars as to tariffs in various Belgium towns are given as above:—

In Switzerland the telephone system has been worked by the Federal Government since 1881, and is considered very popular:—Berne, with a population of 53,000, has 2,025 subscribers; Zurich has 157,000 inhabitants, with 4,400 subscribers; Geneva has 3,264 subscribers out of a population numbering 58,700. The underground cables are of double wire throughout; the overhead, as a rule, single wire. The tariff rates are the same all over Switzerland, namely, £4 and £2. 16s. for the first two years respectively, and £1. 12s. for succeeding years, a charge of one halfpenny being made for each communication, "thus proportioning the expense to the use made of the telephone." Workmen's wages range from 3s. to 3s. 5d. a day of 10 hours. Those of the women operators from £48 to £72 a year, their working day being seven to eight hours in winter and eight to nine hours in summer. Once in 15 days they take night duty, the service being continuous. The following table gives some particulars of progress between 1892 and 1896 extracted from the Swiss Government Trade returns:—

	1892.	1893.	1894.	1895.	1896.
Total length of lines, in miles	3,615	4,208	4,874	5,537	6,524
Total length of wires, in miles	16,569	20,672	25,571	32,980	45,969
Number of nets	124	155	189	225	252
„ stations	14,369	16,929	19,814	23,446	28,198
„ subscribers	12,434	14,675	17,192	20,535	25,090
Number of local conversations	7,123,744	8,382,765	9,981,031	12,402,040	13,436,198
Number of interurban conversations	836,268	1,227,454	1,684,922	2,212,707	2,729,570

From Bavaria reports have been received relating to Munich, Stuttgart and Würtemberg; also from Frankfort, Cologne, Hamburg, Leipsic and Berlin, all of which are, of course, under the Imperial German Telegraph Administration; the conditions, therefore, are pretty uniform, resembling those in the City of Berlin, and need not be particularised. It is worth noting, however, that mention is made in the Munich report that the female operators are required to be of good education, and able to "transcribe and translate without serious mistakes at French or English dictation." Probably this rule applies to all Germany and to other countries—Switzerland, for example—as well. Down to February, 1898, the tariff had undergone no change, and the rumour alluded to by Mr. Provand that the Berlin telephone system yielded 14 per cent. profit was described as premature.

The area of Berlin and suburbs, including Potsdam, has a population of 2,314,451, of which 28,785 are subscribers to the telephone service. It has nine principal exchanges, each arranged for 5,000 to 6,000 subscribers, and 35 public stations, besides 95 at stock exchanges. By means of its trunk wires the capital is in communication with about 350 large towns, both within and without the boundaries of the empire. The system is described as single wire throughout, each connection averaging 1·9 kilometres. The chief features of the tariff are:

(*a*) For each telephone instrument erected within the district of the city telephone system, and not more than 5 kilometres (as the crow flies) from the Central Exchange, an annual rent of £7. 10s. (150 marks).

(*b*) For each telephone beyond the above limit, the distance within which connection is possible being decided by the Imperial Post Office, for every 100 metres of additional wire, or part of that length, beyond the 5 kilometre limit, an additional annual payment of 3 marks.

For messages accepted to be transmitted by telegraph a general charge of 10 pfennigs is made, and 1 pfennig for each word. For three minutes' conversation on the trunk wires, the following examples may be given:—With Prague, 2s.; with Amsterdam, Copenhagen, Rotterdam and Vienna, 3s.; Budapesth, 4s. Exchanges are open from 7 a.m. to 10 p.m. Night service between two subscribers can be arranged for by an extra charge of 8s. quarterly. Capital charge for each wire is estimated at £22. Female telephone clerks are employed at the telephone bureaux, and have the position of officials. They receive a daily wage of 2s. 3d. to 8s., according to length of service; and they perform Sunday duty in turn. The girls have to be of good education, and able to pass an examination. Workmen employed on the telephone lines receive 3s. to 4s. 6d. a day. The Berlin Report concludes with the following remark, which is applicable to the whole of the German Imperial telephone service:—

No statistics can be given relative to the financial position, as in consequence of the union of the postal, telegraph and telephone systems under one Administration, the revenue and expenditure are reckoned under one head, and separate data do not exist. The introduction of a different system of charges is in contemplation, but it is not known if the tariff will be lowered in consequence.

Frankfort-on-Main, with a population of 229,279, has 3,909 subscribers; Leipsic (398,448) has 4,294 subscribers; Cologne (321,564) has 3,784 subscribers; Hamburg city proper has 625,552 inhabitants, of whom 12,064 subscribe to the local telephone system. The service is installed for one year certain, with three months' notice after the end of the first year.

A Telephonic News-agency and Music Hall.—In Vienna a firm calling itself the "Telephone Herald" has acquired a concession for a telephonic news-agency and electrophone business in that city, similar to the one already existing in Budapest. News will be communicated to subscribers by telephone at certain hours of the day, and at other hours recitals—musical and otherwise—will be provided. The concession is granted for 25 years, the undertaking paying the Municipality £100 yearly, and an additional 1s. per subscriber yearly for the maintenance of the lines, and a tax of 5 per cent. levied on the net receipts. At the end of the 25 years the wires and apparatus are to become the property of the municipality, but the latter guarantees the undertaking against competition during the first five years.

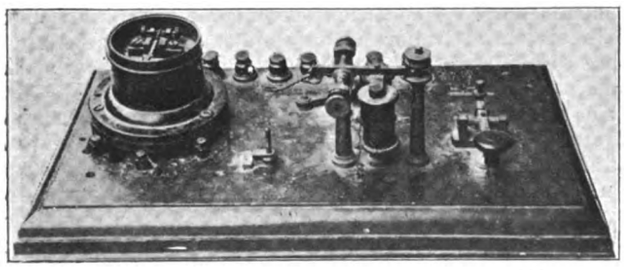
A TELEGRAPHIC RELIC FOUND AT OMDURMAN.

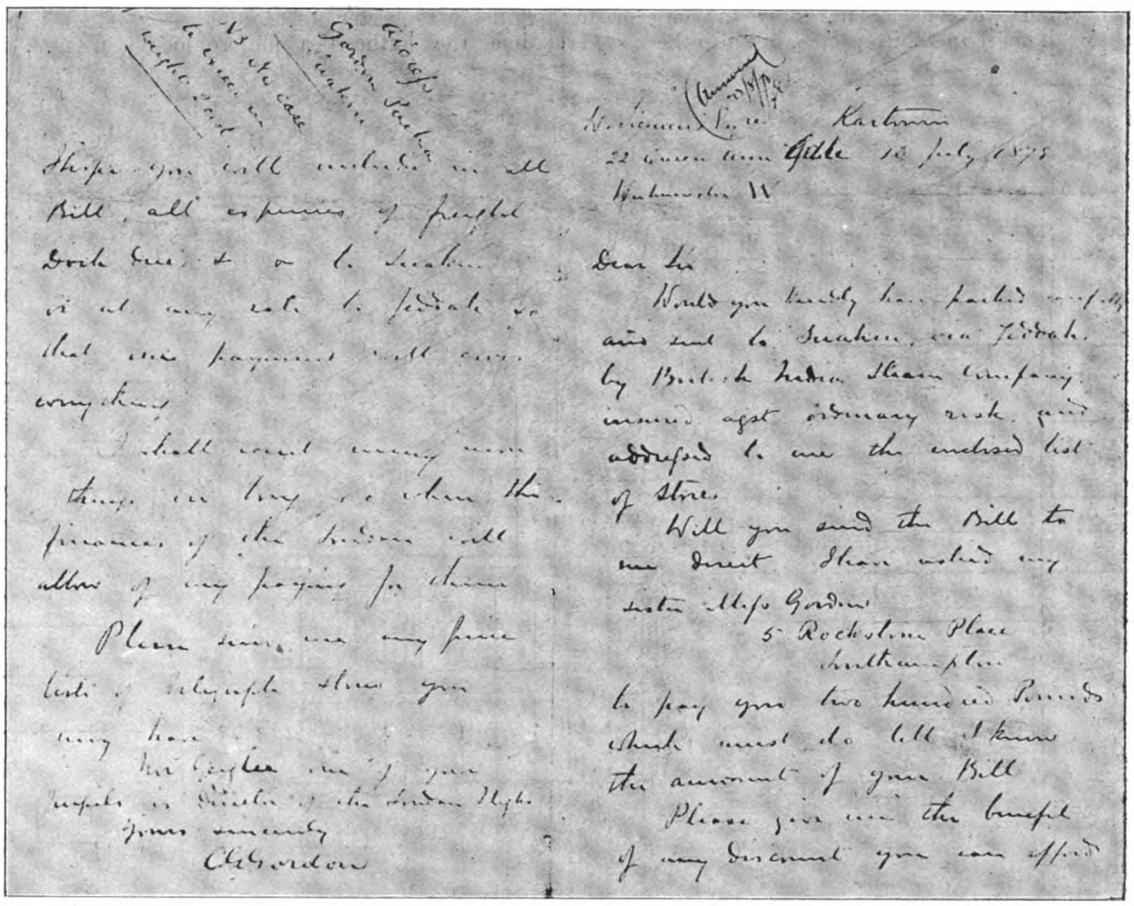
We reproduce below a photograph of an interesting telegraphic relic discovered at Omdurman after the defeat of the Dervishes outside that Soudanese city on September 3, 1898. It appears that after the battle one of the sergeants in the Royal Engineers, working under the Director of Army Telegraphs, of the Egyptian Army, entering the city from the south at the Khar Shambat, noticed an aërial telegraph wire, and, struck by so strange a sight in such a place, followed it



TELEGRAPH SET FOUND AT OMDURMAN, Sept. 3, 1898.

up, and presently found himself at a hut wherein was the instrument shown in the illustration. The instrument was in the charge of an old Egyptian telegraph clerk, who had been held as a prisoner by the Khalifa for the purpose. Since the fall of Khartoum and the building of Omdurman, the Khalifa, it appears, had maintained telegraphic communication between the two cities. From Khar Shambat to the Arsenal, at Omdurman, the line was carried overhead, while from the Arsenal to the dockyard, at Khartoum, a cable had been laid.

In consequence of the relay mounted on the telegraph board bearing the name of Messrs. Siemens Bros. and Co. (Limited) the attention of that firm was called to the relic, and thereby some extremely interesting facts were brought out. Further enquiry showed that this relay was none other than one of 12 ordered of that firm in 1878 by General Gordon. A reduced facsimile of the autograph letter of instruction from General Gordon, dated from Khartoum, accompanies this article, and for this, as well as for our other illustration, we are indebted to the firm in question, in whose possession this valuable letter still remains. The telegraph set was sent home in the condition in which it was found, and is now the property of the officers of the Telegraph Battalion stationed at Aldershot. We understand that it is probable that, by kind permission of these officers, this interesting Soudan trophy will be included in Messrs. Siemens Bros. and Co's. exhibit at the Article Club Exhibition, at the Crystal Palace next summer.



REDUCED FACSIMILE OF LETTER FROM GENERAL GORDON TO W. SIEMENS, ESQ.

W. SIEMENS, ESQ.
22, Queen Ann Gate,
Westminster, W.

(Address, Gordon Pacha, Suakin.)
(N.B.—No case to exceed in weight 2 cwt.)

Kartoum,
13 July 1878.

DEAR SIR,

Would you kindly have packed carefully and sent to Suakin, *vid* Jeddah, by British India Steam Company, insured agst. ordinary risk, and addressed to me the enclosed list of stores.

Will you send the Bill to me direct. I have asked my sister, Miss Gordon, 5, Rochester Place, Southampton, to pay you two hundred Pounds which must do till I know the amount of your Bill.

Please give me the benefit of any discount you can afford. I hope you will include in all Bills all expenses of freight, dock dues &c., on to Suakin, or at any rate to Jeddah, so that one payment will cover everything.

I shall want many more things ere long *i.e.* when the finances of the Soudan will allow of my paying for them.

Please send me any price lists of telegraph stores you may have.

Mr. Geizler, one of your pupils, is Director of the Soudan telegraphs.

Yours sincerely,
C. G. GORDON.

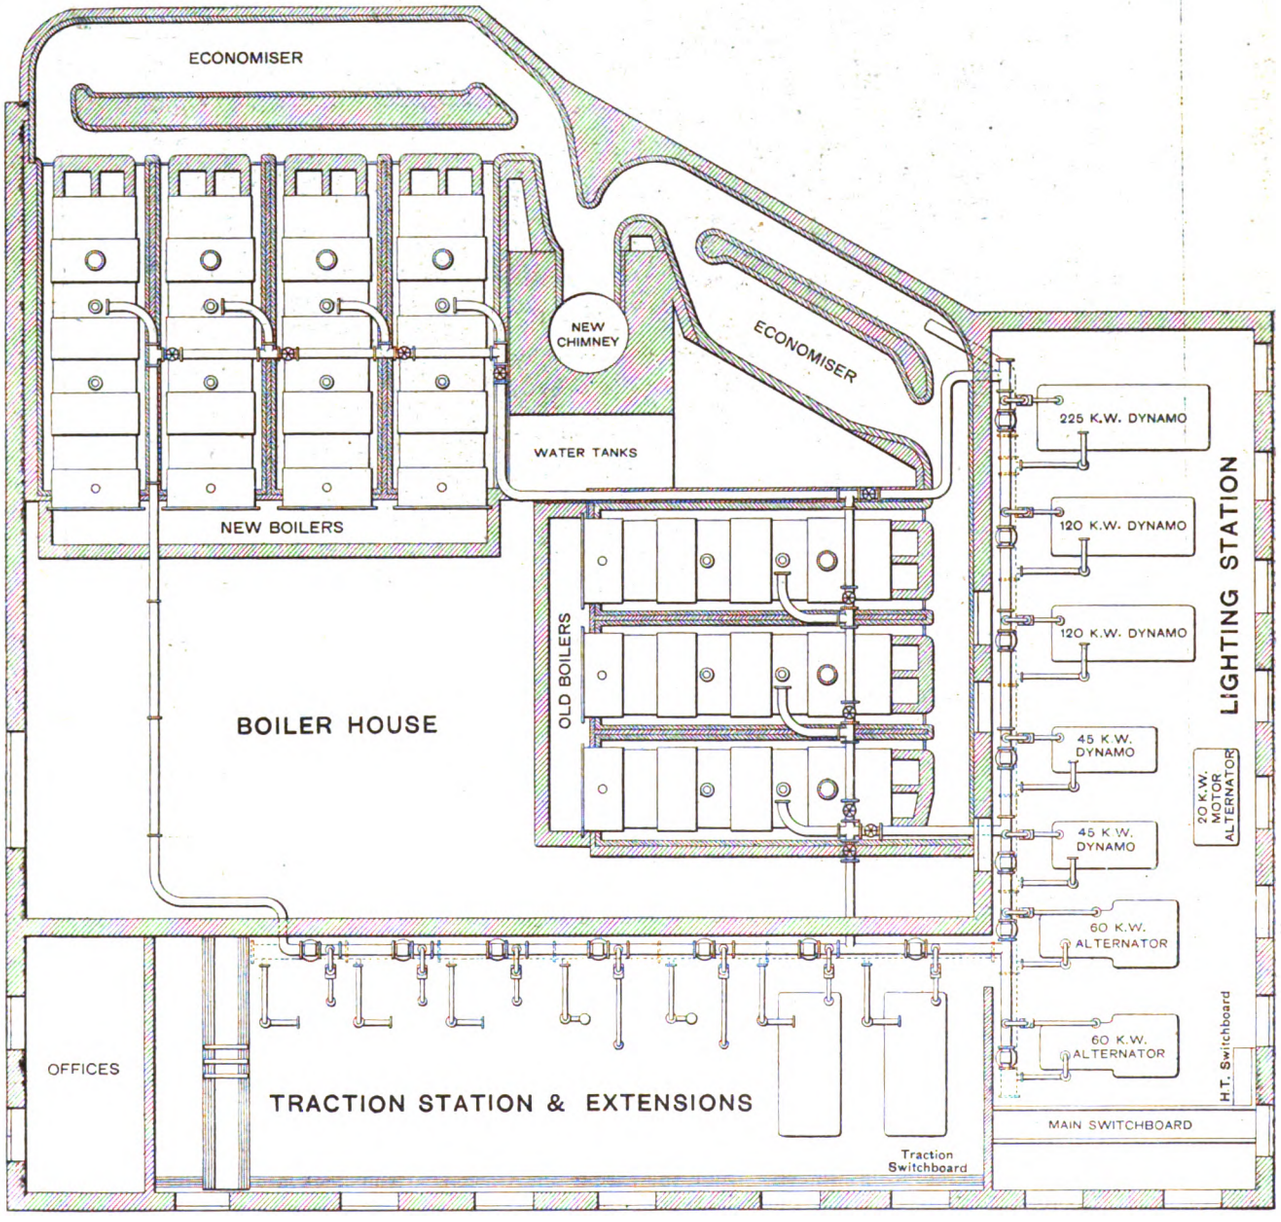
BLACKBURN CORPORATION ELECTRIC TRAMWAYS.

Although the Blackpool electric tramway, which was one of the pioneer electrically equipped lines in this country, has been working with a fair amount of success since the date of its inauguration in 1885, there was until last year, with the exception of the Liverpool Overhead Railway, no other electric line in operation in Lancashire. This is the more remarkable when we consider not only the enterprising characteristics of the Lancashire people, but also the vast net-work of tramways which ramify in all directions outside the larger towns; so far, in fact, have the tramway lines been laid from each town that they often do not end until they reach the terminus of the lines of some other company, whose headquarters are in another centre of population, so that, notwithstanding the fact that Blackburn is some 25 miles distant from Manchester, it is possible to make the entire journey *via* Accrington, the Rossendale Valley, and Bury, by means of tramcars, this particular route covering some 30 miles, whilst across and beyond Manchester the insatiable car traveller could journey for many more miles.

Recently, however, the Lancashire towns have transferred much of their allegiance from steam power and horseflesh to electricity, and last year witnessed the opening of about seven miles of electrically equipped tram lines in Liverpool, and also that of the Blackpool and Fleetwood tram line eight miles long, while the present year sees the opening of four miles of the Blackburn electric tramways, viz., the Preston New-road and Witton sections, and this will in all probability soon be supplemented by the addition of the other sections. And whilst Manchester appears perfectly satisfied to wait what time the authorities philosophically discuss, in polished academic phrases, the various advantages and disadvantages of the overhead trolley, conduit and surface-contact systems, other towns such as Bolton and St. Helens are making rapid progress with their undertakings.



PLAN OF THE BLACKBURN CORPORATION'S COMBINED TRAMWAY AND ELECTRIC SUPPLY STATION.

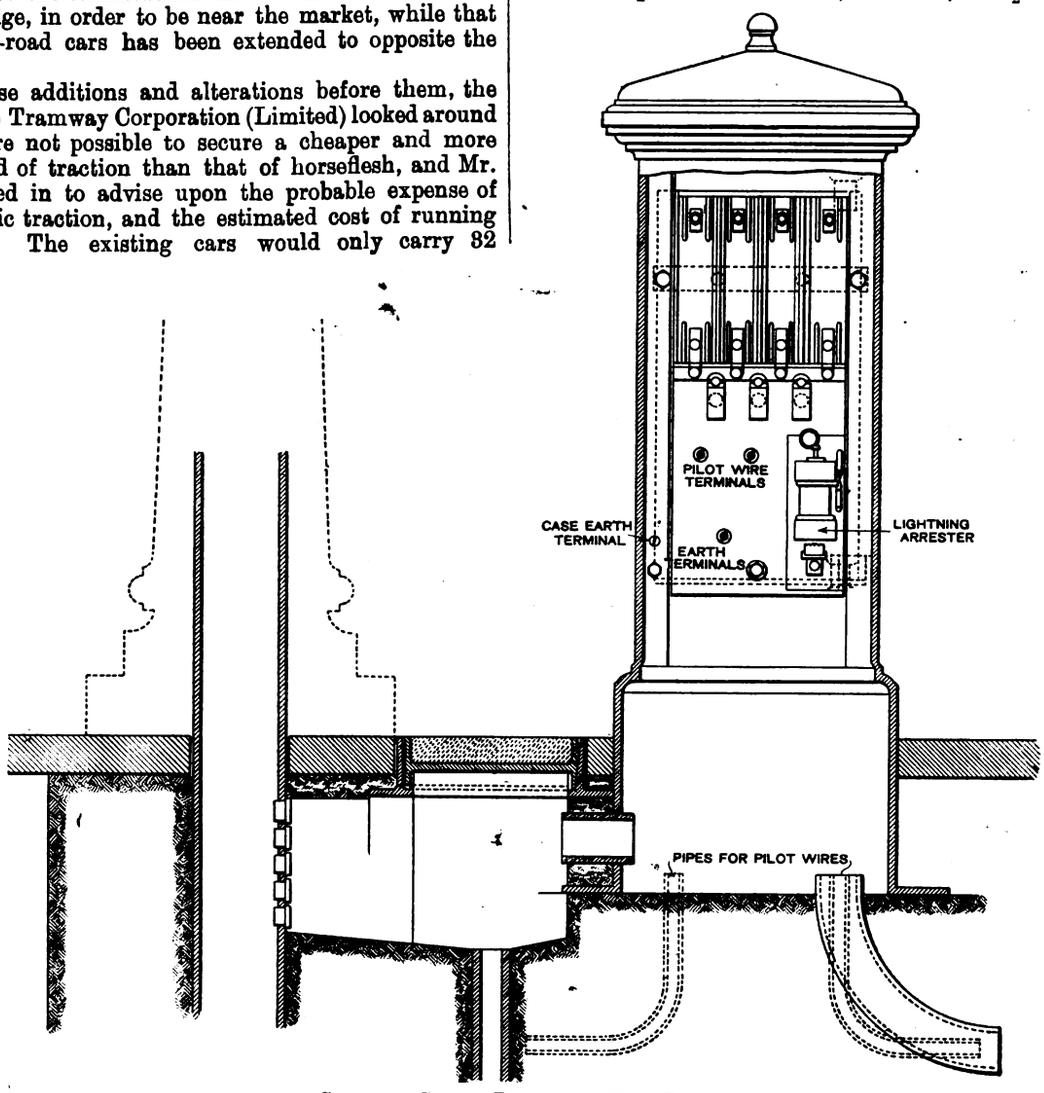
For some time past the claims of electric traction had been advanced in Blackburn, but it was not until 1896 that any definite steps were taken; at this date the Tramway Corporation (Limited) were not only requiring new cars, but also a large part of the track required relaying, whilst, in addition, there were many complaints from the residential district served by the Preston New-road section that the tram terminus was some 250 yards distant from the railway station, which caused considerable inconvenience, especially in wet weather. Another alteration needed was a separate route for

Digitized by Google

the cars on this section on the down journey along Richmond-terrace and past the theatre, in place of both the up and down lines being carried across the open market-place—a source of serious danger when the market was densely packed. It was readily admitted by the tramway authorities that the distance from the station was an inconvenience, and the easiest way to remedy this was to combine the Preston New-road and Witton sections, and to make the cars run through, stopping opposite the station as the town terminus of each section, in place of at Salford Bridge, as heretofore. It may be mentioned here that, although this was at first the scheme proposed, it has since been found advisable to keep the two sections separate, as a ten-minutes service, will be requisite on the Preston-road section, and a quarter of an hour service on the Witton section. Hence the terminus for the Witton cars is retained at Salford Bridge, in order to be near the market, while that of the Preston-road cars has been extended to opposite the station.

With all these additions and alterations before them, the directors of the Tramway Corporation (Limited) looked around to see if it were not possible to secure a cheaper and more efficient method of traction than that of horseflesh, and Mr. Lacey was called in to advise upon the probable expense of adopting electric traction, and the estimated cost of running per car mile. The existing cars would only carry 32 passengers, and it was deemed advisable to increase the carrying capacity to 48, and upon this basis Mr. Lacey drew up his report. After considerable discussions as to ways and means, the Tramway Corporation (Limited) approached the Corporation with the view of obtaining the power from their lighting station, and a suggestion was made, that, as eventually it was most probable that the Corporation would buy out the tramway company, it might be advisable for the Corporation to erect the overhead line and underground feeders. Mr. Lacey, reporting that the cost of renewals and repairs to the motors, as gathered from data obtained in actual practice on other lines would be 0·20d. per car mile for 180,000 miles per annum.

On Sept. 3, 1896, the directors of the tramway company were able to issue a report to their shareholders containing the outlines of a provisional agreement with the Corporation, and about the same time they called an extraordinary general meeting, to obtain powers to proceed further in the matter. The report stated that (1) the Corporation were willing to erect and maintain the generating plant and underground feeders, and to erect the overhead line, and bond the present rails with copper; (2) the Company were to maintain the overhead line erected by the Corporation, or that the Corporation would do this for £100 per annum; (3) that, according to Mr. Lacey's estimate, the cost of motor repairs and renewals would not exceed £200 per annum; (4) that at the price quoted for seven cars, if the amount were taken at 4 per cent. per annum, with a sinking fund repaying principal and interest over twenty years, the cost would not be one penny per car mile; (5) the Corporation would supply power at the rate of 8d. per car mile for 93,892 miles, or 2½d. per car mile if the car mileage be increased to 160,000 miles per annum; (6) that the alterations and additions to the route would be required in any case, and, therefore, need not enter in the discussion. Finally, the report showed a difference in favour of electric traction of 1·30d. per car mile.



Sectional Switch Pillar and Fuse Box.

The directors had fully made up their minds as to the benefit of electric traction, and added various reasons in favour of this method, and the meeting gave them power to proceed further. Negotiations were renewed with the Corporation, and it was decided to increase the number of cars to eight, with a carrying capacity of 60 each; and, finally, a definite agreement was arrived at, and a contract signed between the Corporation and the Company.

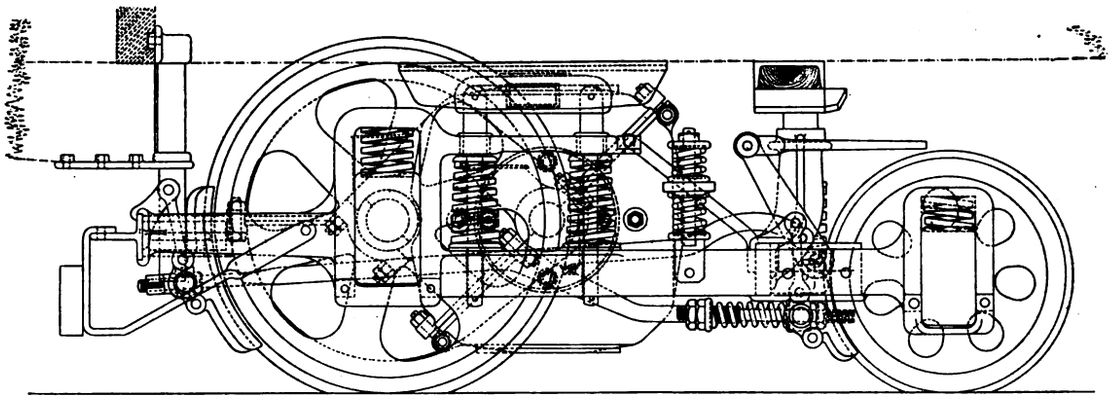
Messrs. Lacey, Clirehugh and Sillar were instructed by the Corporation to prepare specifications for the generating plant and the equipment of the two sections, while the same gentle-

Digitized by Google

men were advisers to the Company for the tramways; the contract for which was placed with Messrs. Siemens Bros. and Co. (Limited) on March 3, 1898.

While these negotiations were being held, and after they were concluded, an agitation arose for the Corporation to purchase the tramway undertaking. A conference was held between the directors and the Corporation, and in the spring of 1898 the terms of purchase were settled; the authority of the Local Government Board to expend the money was obtained in due course, and the agreement was signed on August 24, 1898, by which the Corporation became the owners of the tramway undertaking.

and Robinson engines. The traction sets consist of two direct-coupled steam dynamos, each of 120 kilowatt capacity; the engines are of Messrs. G. E. Belliss and Co.'s 2-crank, compound type, arranged to work with a boiler pressure of 125lbs. of steam, and to give 200 B.H.P. when run at 375 revolutions per minute; the conditions laid down in the specification for governing when the load is suddenly thrown off, and also for steam consumption per kilowatt hour are very stringent, and from the tests so far made the makers appear to have amply fulfilled the requirements expressed in their contract. The engines are of the manufacturers' latest design, fitted with their new open type cylinder valves, and with an

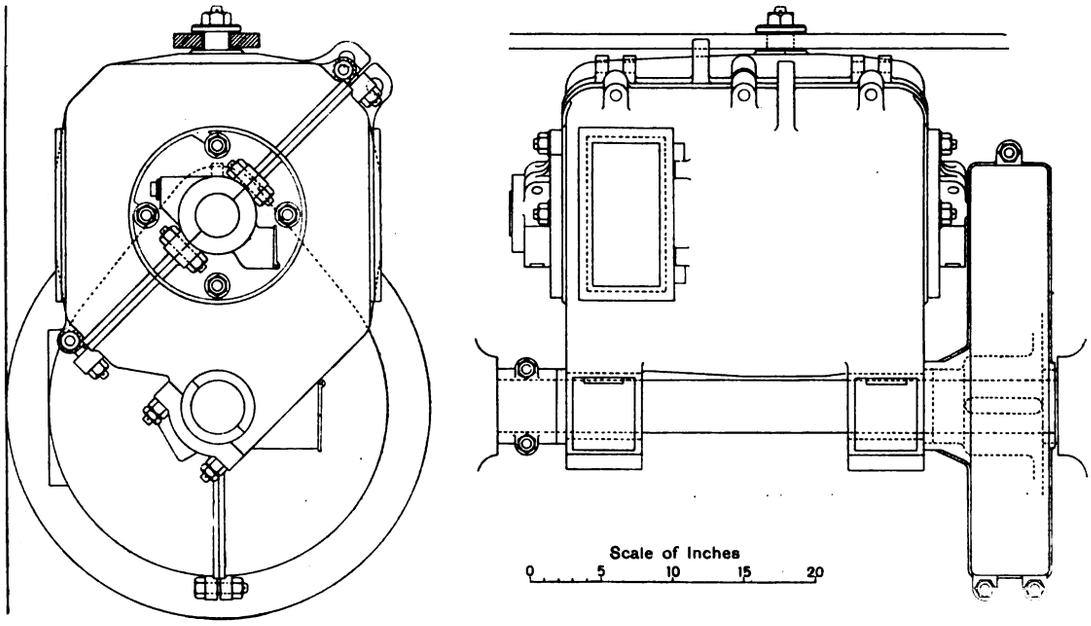


Scale: ¾in. = 1ft.

BRILL MAXIMUM TRACTION TRUCK WITH SIEMENS MOTORS.

The generating station was made as an addition to the existing lighting station, which was most admirably situated for the purpose, being almost in the centre of all the sections—the generating house being built on the site of the old offices and cell room, at right angles to the lighting engine house—while a large part of the yard was roofed in to make an addition to the boiler house, extra room being required for the new boilers, as well as the condensers, economisers, &c., which it was now decided to put down.

oil strainer on each side of the bedplate. Another novelty introduced is the use of an aluminium alloy for the link motion of the throttle valve. The speed varies only 1·9% between 0 and full load. The dynamos were made by Messrs. Siemens Bros. and Co. (Limited), and are of the latest two-pole design, with parallel windings on the armature, and having a commutator at either end. Each of these windings will give 250 volts 240 amperes, and are so connected up that they may be run in series for traction work, or in parallel if



SIEMENS TRAMWAY MOTOR AS USED AT BLACKBURN.

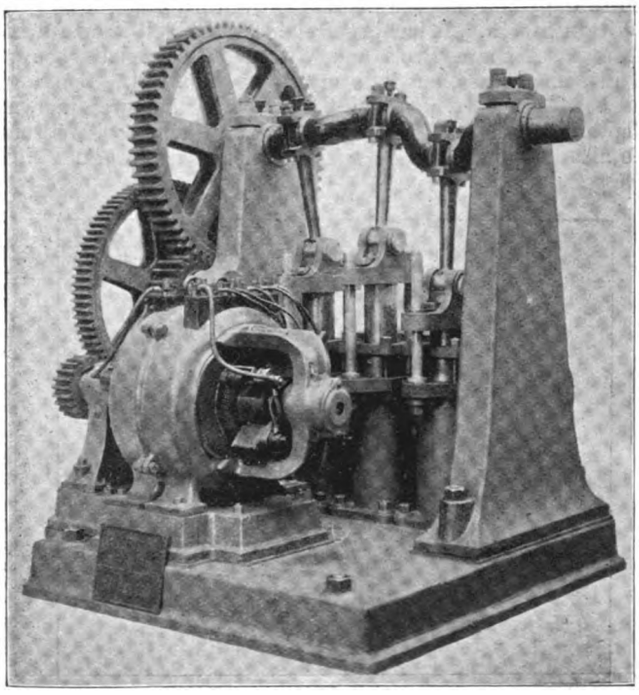
The original lighting station consists of one Mather and Platt direct-current dynamo, with an output of 225 kilowatts, viz., 250 volts and 1,000 amperes, driven by a Belliss engine, four direct-current dynamos of Siemens' make, two with each an output of 200 to 240 volts and 500 amperes, and two with 120 to 150 volts and 800 amperes, all driven by Willans and Robinson's engines, and two Siemens' alternators each 2,000 volts and 80 amperes, which are also direct-coupled to Willans

required to assist the lighting plant. Switch frames for this purpose are fixed at the side of the machines. The machines are compound wound, and fitted with extra long commutators and carbon brushes.

The switchboard, which was made by Messrs. Nalder Bros. and Thompson, is distinct from the lighting board, and is fitted with various recording instruments (as required by the Board of Trade), bus bars, and fuses and switches. The other

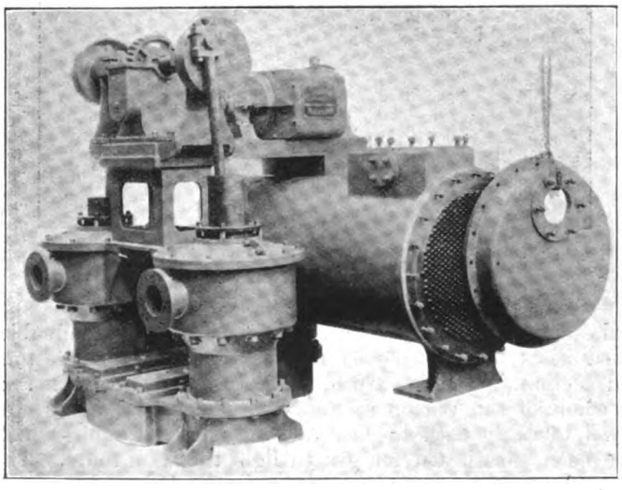
Digitized by Google

instruments are of the Weston type, and consist of two voltmeters (one on the bus bars, and one on the machines supplied with a two-way switch), and six ammeters (one on each of the two machines, and one on each of the four pairs of feeders). In addition there is a leakage ammeter with two scales, the lower one reading to 0·05 amperes, and the higher one to 0·5 amperes. On this board there are also fixed the regulating switches and shunt rheostats for the generators.



ELECTRICALLY-DRIVEN BOILER FEED PUMPS.

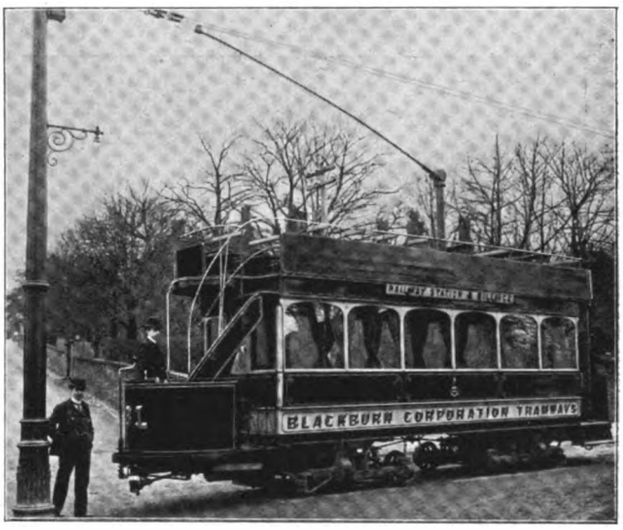
Up to the present time the whole of the engines in the lighting station have been run non-condensing, the exhaust steam from each engine passing into a common main exhaust pipe, and from thence into the chimney. While these additions were being made it was considered advisable to put down a condenser, and also the necessary sets of economisers. The first difficulty that arose was how to get a sufficient reservoir for cooling the condenser water; it was proposed to



ELECTRICALLY-DRIVEN CONDENSER SET.

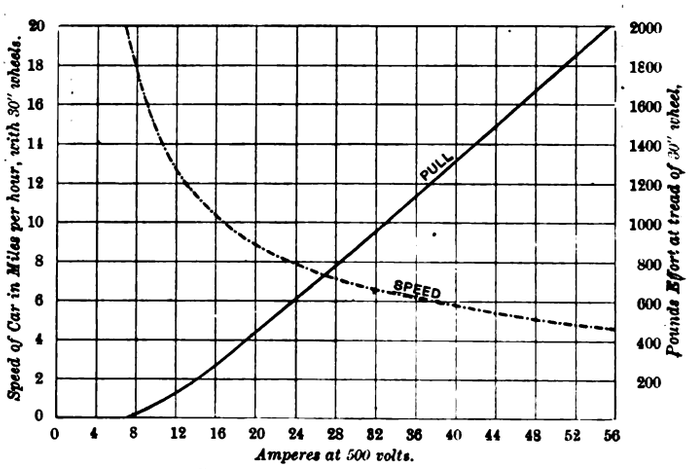
dam the river Blakewater, which flows along one side of the station, and use this for the purpose; but as this stream is not nearly so clear and limpid as it was some 50 years ago, the Health Committee vetoed the proposal, and Mr. Giles, the borough electrical engineer, then proposed several alternative schemes, the one selected being that of arching over the river for a length of some 180ft., and forming a lodge above the river. By an arrangement of sluices this lodge can be supplied from the river, or, if necessary, it can be refilled with water from the town's supply. Mr. Stubbs, the chief borough engineer, successfully carried out the work of forming the concrete floor, the retaining walls on either side and the top and bottom weirs, with their sluices, and the large pipe for the river flow.

The condenser is of the well-known surface type, in which the steam is led by pipes to the outside of a mass of tubes through which cool water is being forced; a centrifugal pump driven by an electric motor is employed for forcing the water through the condenser, the motor being direct-coupled to the pump, and arranged to run at any speed from 850 to 1,000 revolutions per minute. The air pumps, which are two in



MOTOR-CAR FOR BLACKBURN TRAMWAYS.

number, are each 18in. diameter with a 12in. stroke, and are situated at the side of the condenser, and, as will be seen from the photograph, the motor, which is of the four-pole, ironclad type, is carried upon a specially arranged bedplate above the condenser. The air pumps are designed to run at from 30 to 50 revolutions per minute, and the motor from 1,200 to 1,600, the speed being reduced by a worm and wheel gear revolving constantly in a bath of oil; while the thrust of the worm is taken by ball bearings. The condensed steam from the air



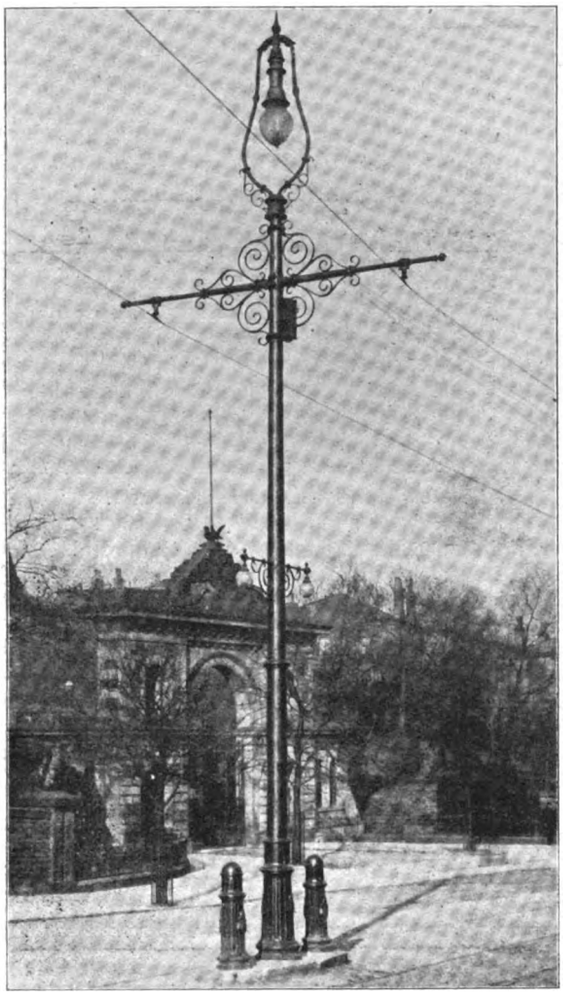
TEST CURVES OF SIEMENS TRAMWAY MOTOR.

pumps is taken to a hot well tank, which is situated at the other side of the boiler house. To this hot well are coupled the suction pipes of the boiler feed pumps; while a galvanised iron vapour pipe is carried from the tank up through the boiler house roof, and the condenser water is carried to and cooled in the reservoir before described.

Particular care has been taken throughout, so that in case of any breakdown to any part of the plant, no serious incon-

Digitized by Google

venience will be felt, hence the exhaust pipes, which are 16in. in diameter, are so arranged that the engines can be run either condensing or non-condensing; automatic valves being inserted in such a position that, should the condensers be shut off for any reason, the exhaust steam would pass through them and find egress up the chimney. For the boiler feed system, there is, in addition to the hot well, a cast-iron tank, placed on the top of the building, which is connected to the town's water mains by means of ball valves; there is also a ball valve connection between this tank and the hot well tank. For the boiler feed there are three pumps, two Worthington steam pumps, which are part of the original lighting plant, and a new three-throw ram pump, driven by an electric motor, with double wound armature and two commutators, so that the two windings can be run either in series or parallel.

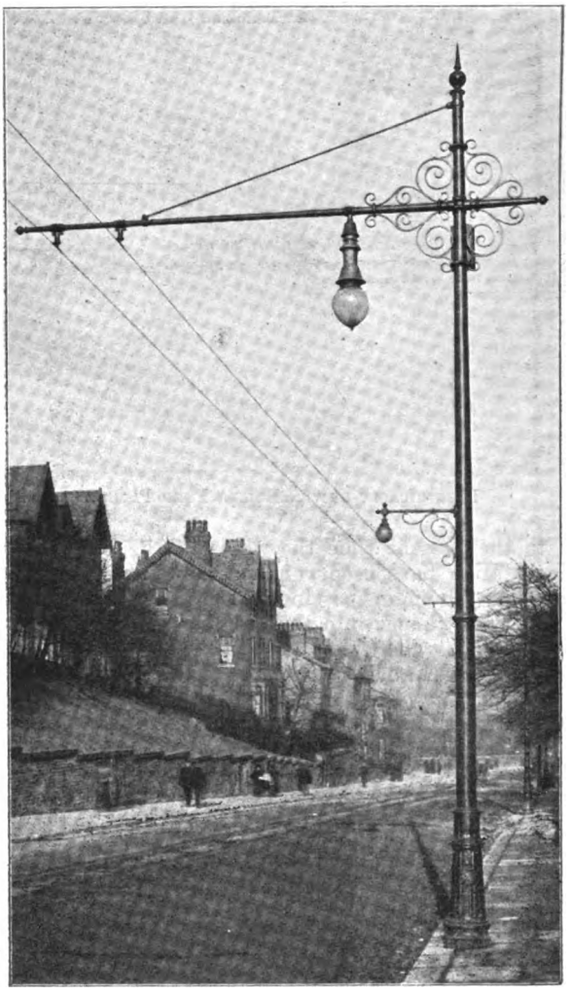


CENTRE-POLE DOUBLE-BRACKET CONSTRUCTION FOR BLACKBURN TRAMWAYS.

There are two banks of boilers, the old bank consisting of three boilers each, 7ft. 6in. in diameter and 28ft. long, and the new bank consisting of two 8ft. 6in. boilers, 30ft. long. These are supplied with Proctor's mechanical stokers, driven by an electric motor, the speed being reduced by means of a Ross's patent reducing gear. The feed pumps are so arranged that either one or all of them may be working at the same time, and by a suitable system of valves the suction water may be taken at will, from the hot well, the tank on the roof or the reservoir; the feed ranges are in duplicate, and arranged so that any pump may be instantly put in connection with either range filter fitted with a McDougall oil bye pass inserted between the pump and main boiler feed range.

Two sets of economisers have been put down, one with 320 tubes for the new bank of boilers, and one with 192 tubes for the old, the scrapers being worked by motors of the enclosed ironclad type. The motors for the air pump and centrifugal pump are of the slotted drum type, with four poles and a series wave winding so that only two lines of brushes are required. The end covers at the commutator end are made to rotate at will, and carry the brushes, which are of carbon, with them; glass windows are also fitted directly over the brushes, so that they may be inspected while running and without removing the cover.

The length of the track is some four miles, and reaches from Billings-lane, beyond Redlam Brow, the former terminus, to Witton Stocks. It has been relaid by the well-known firm of Messrs. Askham Bros. and Wilson with specially heavy rail in some places, but it is mostly of 88lb. rail. Bonding has been carried out effectively with the well-known "Neptune" rail-bond. Messrs. Askham Bros. and Wilson have also supplied the points and special track work. The



SIDE-POLE SINGLE-BRACKET CONSTRUCTION FOR BLACKBURN TRAMWAYS.

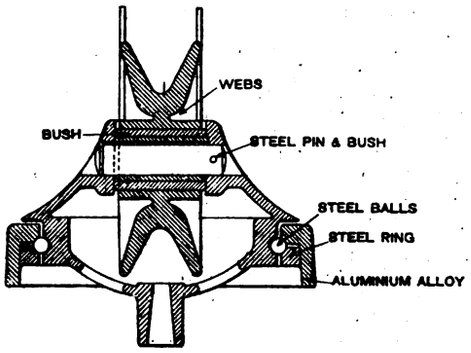
overhead trolley is the system which has been adopted, double-armed posts being employed for about half of the Preston-road section, and single-armed for the remainder of this and the whole of the Witton section, the same posts being employed to carry both the arc and incandescent lamps which have been substituted for gas to light the tram route. The Preston-road section is more or less of a climb from beginning to end, the steepest gradient being 1 in 13 for a distance of some 250 yards, while the Witton section is almost level until Redlam Brow is reached, when the ascent is again 1 in 13.

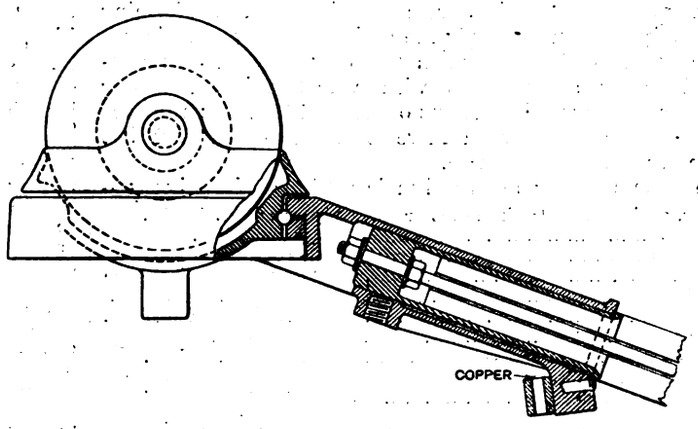
The overhead wire has a cross sectional area of 0·315 square inches, and is carried by cast-iron poles of neat design, with single or double arms, as the case may be. Messrs. Lacey, Clirehugh and Sillar have given very special attention to the design of the poles and arrangements for the overhead line, and we venture to think that an inspection of this part of the

Digitized by Google

work will go far to remove any objections on æsthetic grounds which can be urged to the overhead trolley system.

Where possible, centre posts are used with double bracket arms. The posts are of four grades in strength, in order to meet the varying lateral stresses occasioned by curves, &c. The two lighter types of poles, used for carrying brackets, consist of two lap-welded taper steel tubes shrunk together, with a cast-iron ornamental moulding placed over the joint. The two heavier types, used for pull-off and anchor posts are made up of three parts shrunk together in the same manner. All the poles have cast-iron ornamental bases, and ornamental brackets, their decoration consisting of wrought-iron scrolls, fixed in the four angles between the body of the pole and the bracket arm. The bracket arms vary in length from 5ft. in the centre pole construction to 16ft. in the case of the side pole construction.





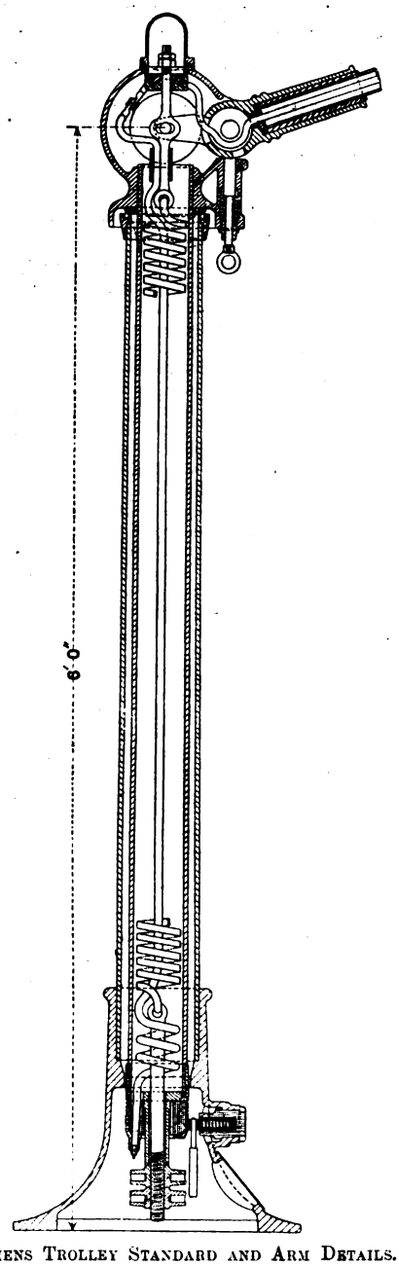
Wherever telephone or telegraph wires cross the track, guard wires of No. 8 gauge galvanised iron wire have been erected over the wire conveying the current for the cars. The two sections are each fed by means of two pairs of feeders, but while on the Witton section there are only three section boxes required, four have been put down on the Preston New-road section, the additional one being required for the down route along Richmond-terrace, which is distinct from the up route across the market and along King William-street, the two routes joining again at Salford Bridge.

The following cables and feeders have been laid :—

Length.	Section.	Distribution.
3,330 yards.	·15 sq. in.	G.S. to Billings.
136 „	·2 „	„ Jubilee-street.
1,240 „	·2 „	„ Witton.
550 „	·2 „	„ „
365 „	No. 310 R.	„ Trolley Wire.
120 „	·3 sq. in.	„ Rail Return.
5,640 „	9/19	(Pilot Wire.)

About every half-mile along the track cast iron boxes are erected on the side of the pavement. The feeders from the station lead into these, and are connected to a bus-bar mounted on a slate base on porcelain insulators. From this bus-bar four high-tension switch fuses connect with the section insulators on the trolley lines by cables leading up the inside of the posts. A lightning arrester is connected between the bus-bars and earth. Terminals from the pilot wire are also brought up on to this slate base for portable telephonic connection and testing purposes.

The cars, which are eight in number, have each a carrying capacity of 60—28 inside and 32 outside. They are of the bogey type, and are propelled by two 25 H.P. motors, which have a large margin of safety, so as to be capable of sustaining for prolonged periods a considerable overload. The motors are of the four-pole enclosed type, with a series-winding of the armature, and, consequently, only two lines of brushes; the machines are shunt wound, a starting switch and regulating resistance being placed on the platform at either end of the car. The motors are placed directly under the car, and are connected to the driving axles by means of machine-cut steel spur wheels, this gearing being protected against mud and dust by being enclosed in iron casing; the brushes are of carbon, and are fitted in holders of Messrs. Siemens' latest design. The cars are each lighted externally and internally by means of ten 16 c.p. lamps, working at 100 volts pressure.



SIEMENS TROLLEY STANDARD AND ARM DETAILS.

These are run on two parallel circuits, each consisting of five lamps in series, and are arranged so that alternate lamps only are on the same circuit.

Digitized by Google

As will be seen from our photographs, the same posts are made to carry both the arc and incandescent lamps. The former are of the enclosed long burning type and were made by the Davey Electric Construction Co.; they are supplied with an alternating current of 100 volts, and are fitted with a choking coil; the current is obtained from the sub-station transforming chambers put down to supply the various shops and residents in the districts through which the cars run. The incandescent lamps are supplied with a 230 volt alternating current, and are run in sections of about 12 lamps; they are each of 32 c.p. lamps when there is only one to a post, but of 16 c.p. when there are two.

The principal contractors and makers of plant have been:—

Cars, equipment of track and motors ...	Siemens Bros. and Co.
Boilers	Yates and Thom.
Engines	Belliss and Co.
Switchboard	Nalder Bros. and Thompson
Rails, points, &c.	Askham Bros. and Wilson.
Trucks	Laing, Wharton and Down.
Car bodies	Milnes and Co.
Engine house, plant and switchboard ...	Siemens Bros. and Co.
Condensers, pumps, economisers, enclosed motors and pipes	Ashton, Frost and Co.

As mentioned, Messrs. Lacey, Clirehugh and Sillar have acted throughout as the consulting engineers.

WIRELESS TELEGRAPHY.

The following is a report of the proceedings on the occasion of the second reading of Mr. Marconi's Paper on "Wireless Telegraphy," before the Institution of Electrical Engineers, on the 16th inst.:—

Mr. J. W. SWAN (the President) said that they had with them that evening, in the person of Sir Henry Mance, another inventor of wireless telegraphy. He was the inventor of what was known as the "heliograph," which was a method of wireless telegraphy which depended upon the same general principle as Mr. Marconi's, viz., the agitation of the luminiferous ether as a means of sending signals. He had been informed that under favourable conditions (these conditions being that the apparatus must be very highly elevated, perhaps on a mountain top) it had been possible to send signals a distance of 60 miles. But this, of course, was not the limit, because they had evidence that light passed through millions of miles; but a telegraphic system of that description had the disadvantage that it required a very elevated position, and even with that advantage it was not always possible to get the signals to pass. It required a transparent atmosphere, and he need not remind those who lived in this city of dreadful night that it did occasionally happen that they did not have a transparent atmosphere, and under these conditions (which had been very frequent lately) he thought it would have been quite impracticable to carry on this system of wireless telegraphy. One of the great points of the Marconi system was that it was possible to transmit signals through the densest fog and even through a London fog or obstructions of the nature of mountains. These were very great advantages, and he thought the whole world was greatly indebted to Mr. Marconi for the practical results he had obtained.

Mr. MARCONI, in replying, thanked the Chairman for his kind remarks and the audience for the interest they had taken in the subject, and for the kind manner in which they had received his Paper; this being the first he had ever read in the English language. He was glad to note that many results obtained by Dr. Fleming coincided with his experience. He (Dr. Fleming) had found that a well made coherer was not the uncertain, treacherous and unreliable instrument which it had so often been said to be, and he had also noted the advantages obtainable by the use of the vertical conductor. The reason why the employment of oil in the spark gap was no advantage—rather, in his opinion, a disadvantage—was because oil seemed to offer a very variable opposition to the passage of the discharge Thus, if the oscillator containing the oil had not been used for some hours he found that the potential required to pass a spark through it was far greater than it would be after a few moments of work. It seemed as if the continuous discharge maintained a kind of channel in the oil, after the first discharge, and therefore, if the receiving instrument was at a considerable distance, *i.e.*, near the limit of the distance over which it was possible to signal, he found that while the dots, which were produced by single impulses, were all recorded, the dashes in great part missed. When a comparatively large capacity was connected to each end of the discharging spheres, air seemed to be quite an ideal substance in the spark gap, and curiously enough he had obtained better and absolutely constant results if the spheres were not polished. He had found that the use of mercury in the coherer was necessary in order to obtain the best results. He also found it advantageous—or, as far as commercial work was concerned, necessary—that the tube should be exhausted to about 1mm. The tubes he made were always tested over a distance of 18 miles, and if they failed to give good signals at that distance with a moderate length of vertical wire, they were not considered satisfactory. Although signals had been at times received over a distance of 18 miles by non-exhausted coherers, no reliable results had been obtained in such cases. Probably if they employed a vertical wire 200 feet high instead of 75 feet, they would obtain fair results with non-exhausted coherers, but a mast 200 feet high would not be a very practical piece of apparatus. He had also noticed that tubes of coherers containing air were always decreasing in their sensitiveness, and this would not do for commercial installations. In reply to the questions asked by various members as to the necessity of having the earth connection, his experience had been that in order to obtain the greatest possible distance with a given height, an earth connection at both receiver and transmitter was necessary. If, however, suitable capacities were substituted for the earth, communication could still be maintained, although at a somewhat shorter distance. The results obtained, when capacities were used in place of an earth, were similar to those obtainable when a condenser was inserted in the earth connection, and he believed the result of connecting the earth terminal of one of the instruments to a capacity area was equivalent to inserting a condenser of similar capacity into the earth connection. As had also been noticed by Mr Gavey, he found that a small capacity on the earth wire of the receiver was sufficient to obtain good results, whilst a much larger capacity was required at the transmitter. The fact that signals could be obtained without earth connection might seem, at first sight, as if proving that the earth had nothing whatever to do with the conducting of oscillations from one station to another, the possibility of which he had pointed out in his Paper. But it seemed to him that even if a great part of the oscillations were conducted by the earth, the fact of disconnecting one or both instruments from earth and substituting for the actual metallic earth connection a capacity area was no proof that the earth was unnecessary. With no capacity on the earth end of the coherer or radiator, it was impossible to obtain results; and if a capacity must be there—and especially if it be near the earth or any earthed conductor—was not that equivalent to a condenser inserted into the earth connection? If they considered the very rapid oscillations with which they were dealing, it would be found that a very small condenser, say, $\frac{1}{100000}$ m.f. capacity, was more than ample at the receiving end for allowing the dielectric currents to pass from or to the earth. It was his opinion that unless they could transport the whole apparatus to a very considerable distance from the earth or any earth conductor, it would be impossible to come to any definite conclusion as to whether mother earth was, or was not, taking a very important part in this phenomenon, and he took it that any capacity area so connected to the instrument was only a plate of a condenser, of which the other plate was the earth. It might surprise many of them when he stated that with the instruments connected to earth, if they disconnected the vertical conductor from the receiver, they could still receive good signals at distances of many miles. In this case one might say that the effect must necessarily all come from the earth connection, but it was found that the lower end of the vertical conductor must be in proximity to the receiver, and from this lower end the oscillations jumped across the gap in the same way as the oscillations would traverse the insulation separating the two plates of the condenser. Over a distance of 14 miles he had got signals even if the vertical conductor was separated from the terminal of the receiver by a gap more than 1ft. wide. In this case a metal plate, about 1ft. square, was attached to the terminal of the receiver, and to the end of the vertical wire. This seemed to show that actual metallic connection between certain parts of the instruments was not always necessary, as, with these high frequencies, oscillations could bridge over gaps which might exist in certain connections, in the same way as they traversed the dielectric of the condenser. The results showed that it was not necessary to have an actual metallic connection with earth, as this again could be effected through the ether. It was therefore of no great importance for installations, such as the Fastnet rock, to have what telegraphists call a "good earth," as a capacity would be quite sufficient. In the case of the Fastnet lighthouse, its being built mainly of boiler plate would afford an excellent capacity to which to connect the earth terminal of the instrument. Mr. Millar stated that he had noticed these results in experiments on a smaller scale which he had carried out. He (the speaker) explained Captain Brett's statement that the result of the instruments working at the South Foreland lighthouse without an earth connection came as a surprise to him, by stating that the surprise was not occasioned in view of no earth connection, but because he did not think there was sufficient spare power to enable the receiver to work when the earth connection was substituted by such a small capacity as was used in that instance. Mr. Granville had informed him that it would be impossible to get a radiating or receiving conductor at the Fastnet rock more than 10 or 20 feet away from the mass of conducting metal, but in such instances as the Fastnet, the line would only need to be a small one, and he did not anticipate any difficulty in applying his system to such a place. At Rathlin Island the conductor was suspended from the lighthouse and very near to it, while on the Royal yacht, the wire was sometimes nearly within sparking distance of one of the funnels, but good results were always obtained. Again, on the East Goodwin lightship the wire was very near the iron mast of the ship, and surrounded by a great number of wire stays. In reply to Mr. Gavey's remarks on the question of the law of the height of the vertical conductor, this he had communicated to Mr. Preece on November 10, 1896, as mentioned in his Paper, and it had also been fully discussed in the Italian technical press.* It was very interesting to know that Mr. Gavey, working quite independently at Dover, came to exactly the same conclusions as to this law. In connection with the difference in the height required when working over land and over sea, he had no doubt that over water or over perfectly open space it was easier to telegraph than over undulating land, but his experience was that the difference was by no means so marked as Mr. Gavey had mentioned, viz. 35ft. over water and 50ft. over land. At Salisbury, in the autumn of 1897, he found that 30ft. of vertical height was sufficient for a distance of one

* See *l'Elettricista*, August, 1897, and work of Della Ricia in the *Rivista di Artiglieria a Genio*, 1897-98. Also Lecture of Prof. Bougiovanni at Ferrara, November, 1897. [*See* also a review of Della Ricia's work in *The Electrician* of November 25, 1898, p. 160.—ED. *E.*]

Digitized by Google

mile, and it was not until the apparatus had been considerably improved that he had been able to reduce the height at sea to less than 20ft. He was not at all certain that this height would not carry them practically the same distance over land as over sea, although he quite believed that over water the maximum results would always be attained. He had mentioned in his Paper that when signalling between Osborne House and the Royal yacht, even with nine miles of land intervening, the average height of the mast had been 90ft., which gave the figure of 30ft. for the first mile, although all these nine miles were not across clear space. His experience was that it was unnecessary for the stations to be fixed at a height over the water to obtain good results. Indeed he was not at all sure whether having the base of the wire on a height was an advantage. At Spezia the land station was on the sea level, and at Kingstown during the Regatta, the station had been only about 20ft. above the water level —the corresponding station being on a ship in the Irish Sea—and it was worthy of note that it was off Kingstown that the greatest distances yet reached in telegraphing over water, that is, 25 miles, had been obtained. At Alum Bay the station was at a height of 200ft., but at the corresponding station at Poole the pole was fixed in the sand below high-water mark. As to whether 20ft. was a practical working height and had a safe margin, he could confidently state that it was. As a matter of fact, they were at the present moment working across 18 miles with 75ft., and this could readily be reduced by 10ft. at each end if there were any object in doing so. In connection with reflectors, he noticed that Mr. Gavey had suggested the undulations of the ground as the cause of the failure of the experiments with reflectors at Dover at greater distances than half-a-mile. This did not, however, coincide with his own experience, as his first experiments carried out with much smaller reflectors were made at Salisbury, and there he found no difficulty in signalling up to a distance of 1¾ miles. He quite agreed that attention should be turned to this subject, and hoped to give more consideration to it shortly himself. With reference to tuning, he quite agreed with Mr. Gavey that it was difficult to obtain good results by altering the length of the vertical conductors, or even if the conductors were wound up into a coil or solenoid, but there were other methods which he was confident would allow tuning, and he intended to continue on a large scale some experiments which he had made on a small scale some time ago, in this connection. With lightships, however, he thought tuning would be a disadvantage, as if a ship A was tuned with a ship B, another lightship, which might be tuned to another note, could not communicate with either of them. As soon as the cross-channel service was started he intended making large scale syntonic experiments. He thought Mr. Gavey rather over-estimated the effects of lightning. Although numerous vertical wire installations had been working for nearly two years, none had ever been struck by lightning. On the coast of Italy, where many installations had been erected, and where thunderstorms, especially in the summer, were much more frequent and violent than in this country, nothing had ever happened. A lightning conductor higher than the vertical wire could be fitted in the ordinary way if there was any desire for it, without in any way interfering with the efficiency of the system. On board the Royal yacht "Osborne" the top of the wire was well below the top of the lightning conductor. They had, however, anticipated the possibility of danger by making an arrangement whereby the assistant in charge had never to touch or handle the aërial wire, which was always connected to earth both when transmitting and receiving. This prevented any accumulation of atmospheric electricity on it. The method he had adopted for screening the receiver from the violent surgings of the transmitting apparatus was as suggested in his patent of 1896. All the receiving apparatus was enclosed, with the exception of the inker or recorder, in an earthed metallic box. As some oscillations picked up by the inker and connections might, by travelling along the leads, injure the coherer, he choked off such effects by interposing suitable choking coils between the inker connections and the terminals of the receiver. These choking coils consisted of a few turns of insulated wire, each layer being separated from the next by means of sheets of tin foil, in electrical communication with the box. The earthed tin foil prevented oscillations from passing inductively from one turn to the other of the choking coil. In connection with the use of reflectors with the vertical wire system, he was of opinion that, considering the length of wave emitted—calculated by Prof. Ascoli to be four times the length of the vertical conductor—the reflectors would require to be very large indeed to be effective. As to the effect of screening or interposed objects, he had described in his Paper several stations in which hills did not in any way interfere with the transmission. Captain Jackson, of H.M.S. "Defiance," Devonport, had obtained good results even with battleships intervening between the stations. An installation had also been worked by Lieut. Della Ricia, in Brussels, between positions 400 yards apart, although nine houses, and an hotel constructed in great part of iron, intervened between the transmitting and receiving apparatus. As to Mr. Granville's question, whether he found it necessary to use accumulators for working the induction coil, although he was now using accumulators at several stations, so far they had only been employed experimentally. Excellent results had been obtained, up to the present, with dry cells alone, and the 100 M-size cells had remained efficient at Alum Bay for rather more than ten months. The lightship was also worked on dry cells, and he was confident that the battery would last for much longer than a year. The installations at Osborne House, on the Royal yacht, and at Kingstown had been worked by batteries of 50 cells, no accumulators having been used. As to whether the transmission of signals was effected purely by radiation, he was rather uncertain as to the reply that should be given. Doubtless over clear space radiation was the chief factor. He had noticed, and he believed that Dr. Fleming had also noticed the same thing, that if the two conductors were slanting it was necessary that they should be parallel to each other in order to obtain maximum results. Many more experiments, however, would be necessary to throw more light upon this. The reason why messages were not sent over greater distances at public demonstrations was that he did not think it desirable to divide his audience, as it would be necessary to have some of them at the other station. Many of the members of the Institution had seen the system working over long distances, and if any others would care to inspect it, he would be pleased to give them every facility. In reply to Mr. Miller's question as to what was the best composition of the coherer filings, he said that nickel filings mixed with a small percentage of silver and mercury was the best. With regard to the waves being reflected by the surface of the sea or land, he was inclined to believe that this reflection might possibly have much to do with the results, although he had no sure proof or experimental test as to how much or in what measure they did. Prof. S. P. Thompson's suggestions had come as quite new to him. He hoped to have an opportunity of testing this theory experimentally. But he would remind Prof. Thompson that the earth need not always be at the bottom of the aërial conductor, as during certain experiments he had had the earth at the top. At Alum Bay he had suspended the conductor over the edge of the cliff, the instrument and earth connection being at the top, whilst the lower end of the conductor, which was 100ft. long, hung free in space. When the wire was held at about 30ft. from the cliff, it was quite easy to speak to Bournemouth 14 miles distant. It was interesting to note that in this instance no pole was used to suspend the wire as the cliff fulfilled that purpose. This showed that in the case of lighthouses it was unnecessary to have a pole to suspend the wire. They could suspend it from the terrace of the lighthouse and fix it at the lower end or let it dangle in space.

DINNER TO MR. CHARLES GERHARDI.

In recognition of friendly services rendered from time to time to the Spanish nation by Mr. Ch. Gerhardi, His Majesty the King of Spain, through the Queen Regent, was recently graciously pleased to honour Mr. Gerhardi by conferring upon him the Royal and distinguished Order of Knight Commander of Isabel la Católica; and on Saturday evening last, at the Freemason's Tavern, Great Queen-street, London, a party of Mr. Gerhardi's personal friends foregathered to congratulate him upon this auspicious event, and to convey to him at the same time their recognition of his worthiness of the high honour thus bestowed. The chair was occupied by the Iltrmo. Señor Don Nicasio E. Jauralde, financial delegate for Spain in this country, who was supported by Mr. G. Allen, Mr. W. H. Axworthy, Mr. J. Bass, Mr. W. D. Bayley, Mr. A. Brown, Mr. T. A. Bullock, Mr. R. Collett, Mr. J. F. De Cossio, Mr. J. W. Dixon, Mr. George Draper, Mr. L. Franken, Mr. J. Gavey, Mr. G. H. Gerard, Mr. C. Gerhardi, junr., Mr. J. Gramaggini, Mr. R. Kaye Gray, Mr. W. Hibberdine, Mr. A. W. Hibberdine, Mr. W. W. Howell, Mr. F. Howell, Mr. G. C. Jack, Mr. A. Jauralde, Mr. J. W. P. Jauralde, Mr. J. Jeffery, Mr. A. R. Jurado, Mr. S. Laborda, Dr. Ledlie, Mr. C. Lee, Mr. W. F. Lewin, Mr. R. Lopez, Mr. J. F. Mills, Mr. F. Munk, Mr. V. C. Nevares, Mr. W. Norton, Mr. E. Parsoné, Mr. F. T. Preddle, Mr. J. Rippon, Mr. H. A. C. Saunders, Mr. A. T. Serrano, Mr. H. St. L. Smith, Mr. W. Marsden Smith, Mr. J. Swann, Mr. F. O. Thompson, Mr. Geo. Tucker, Mr. E. Walden Vincent, Mr. W. Vincent, Mr. A. H. Walton, Mr. Fred. Ward, Mr. J. Y. Watson and Dr. Wholey.

After an excellent and well-served dinner the toasts of "The Queen" and "The King of Spain and the Queen Regent" were cordially drunk.

The CHAIRMAN then gave the toast of "Our Guest," and referred in feeling terms to the many opportunities which had arisen during the 27 years which had passed since Mr. Gerhardi first became associated with Spain and her people through the Direct Spanish Telegraph Co., and especially in the recent past, and how Mr. Gerhardi had always availed himself of these opportunities to show his sympathy for Spain, both in her joys and her troubles. Their guest that evening was as well-known in Madrid as in the city of London. He had many friends in Spain, and in the dark days now happily over the little friendly services which Mr. Gerhardi had been able to render to Spain, not only in his official capacity, but as a private gentleman, had come especially under the notice of the King and the Queen Regent, and, as some recognition, the Order which they had met to congratulate him upon having received had been bestowed, and most worthily bestowed, upon a true friend to Spain. He was sure they all hoped that this was the stepping-stone to greater honours—and further festivities to celebrate them.

Mr. GERHARDI, on rising to respond, had a hearty reception. He said he saw around him very many of his old friends in the telegraphic service, in which he had laboured for 42 years. He was, he believed, the *doyen* of the telegraph service (so far, at least, as active service was concerned). To these old friends and to all who had assembled that evening he could only say how grateful he felt. He could not live long enough to merit all the kind things that had been said of him. He fully appreciated the high honour that had been conferred upon him, and accepted it as a token of regard for any little service he might have been able to render to Spain in her time of trial as well as in the more pleasant days of old. He had always succeeded in ingratiating himself with Spaniards both in England and in Spain. He felt sure that the results of the recent war would be to leave Spain invigorated and concentrated, and he looked forward to her speedy regeneration. In connection with his telegraphic work, Mr. Gerhardi mentioned that it was he who had wired the news of the victory of Inkerman, and the man who had received this message in England had been good enough to prophesy that great things were in store for the man who had notified this noble victory. He felt that the prophecy had been verified by the high honour of which he had been the recipient, and by the gathering of his friends around him that evening. He was deeply sensible of all their

Digitized by Google

kindness, and thanked them heartily for the way in which the toast of his health had been received.

The remaining toast of "The Chairman" was proposed by Mr. E. WALDEN VINCENT, and was warmly received. Mr. Vincent referred to the services rendered to Spain by Señor Don Jauralde, and how highly he was respected in the English capital by all who came in contact with him either in business or in social life.

The proceedings throughout were of an enthusiastic character.

ELECTRICITY WORKS ACCOUNTS.

Liverpool Overhead Railway Co.

The subject of our first table this week is the accounts of the last half-year's working of the Liverpool Overhead Railway. Parallel with the several values for this period we repeat those referring to the corresponding period of 1897, for purposes of comparison. With regard to the capital account, the total amount expended up to December 31st last amounted to £748,152, representing £111,400 per mile of working railway. Of this latter figure £98,800 is the proportion spent on the line, and £17,640 per mile the amount spent on working stock and the generating station.

The total capital received stands the same as in the previous year, the loan capital of £170,000 having been borrowed on terminable mortgage debentures at 4 per cent.

Compared with the corresponding period in 1897 the train mileage has slightly increased—about 0·5 per cent.—while the number of passengers carried shows an increase of 427,431 or about 9·6 per cent.

The revenue and expenditure account has a most gratifying aspect. Although the revenue per passenger has slightly dropped, the receipts per train mile have risen from 24·2d. to 26·23d.—about 8·4 per cent. On the other hand, the expenditure per train mile has remained practically steady at barely 1s. 3d.

It should be pointed out, however, that, with the exception of the item "maintenance of way, works and stations," all the other main divisions of expenditure have increased. "General charges" were lower, but only through the fact that in the 1897 half-year a payment of about a penny per train mile was made to the Liverpool Tramways Co.

As to the financial results, a working profit of £17,623 has been made, representing 2·36 per cent. of the mean capital during the period. Out of this sum £1,500 has been voted to the depreciation fund, and £3,400 paid as interest on loans. The remainder with the balance from the preceding half-year has enabled a dividend at the rate of 4 per cent. per annum, to be paid on the Ordinary shares for the half-year, after satisfying 5 per cent. per annum on the Preference shares.

It should be noticed that, under "General charges," £100 has again been paid into the contingent fund from revenue. This fund now stands at £700, and the renewal fund at £12,400.

An arrangement has been concluded between the Company and the Waterloo and Seaforth and Great Crosby District Councils for the working of a tramway extending from Seaforth station to Cook's road, Crosby, a distance of 2½ miles. The local authorities are to lay the road and rails, and the Company provide the electrical equipment, maintain the rails, and pay the district councils 8½ per cent. per annum interest for 20 years on the cost of laying the rails. This rate covers the interest and sinking fund on the estimated cost. At the end of the above period (when the sinking fund is wiped off) the annual payment would be 4 per cent. for the remaining six years of the lease. The estimated total expenditure by the Company on the equipment is £25,813.

The table given below indicates the growth of the traffic on the overhead line since it was opened on March 6, 1893 :—

Half-year ended	Passengers.	Train mileage.	Dividend.	
			Preference.	Ordinary.
Mar. 6 to June 30, 1893 ...	1,370,742	...	...	...
Dec. 31, 1893	2,475,639	243,539	5%	1%
June 30, 1894	2,861,437	...	5%	1%
Dec. 31, 1894	3,641,379	314,472	5%	2%
June 30, 1895	3,460,060	311,346	5%	2½%
Dec. 31, 1895	3,780,375	321,417	5%	3½%
June 30, 1896	3,739,575	313,010	5%	2¾%
Dec. 31, 1896	3,919,134	320,993	5%	3%
June 30, 1897	4,269,260	363,399	5%	3%
Dec. 31, 1897	4,467,490	371,773	5%	3½%
June 30, 1898	4,472,941	362,690	5%	3%
Dec. 31, 1898	4,467,490	371,773	5%	3½%

City and South London Railway Co.

The accounts analysed are those for the half-year ended December 31st last. For purposes of comparison we have repeated the analysis of the accounts for the corresponding period in 1897.

The share capital received amounts to £1,146,348, of which £816,548 has been raised on Ordinary stock and shares, and £329,800 on Five per Cent. Preference shares. £187,701 represents the loan capital, which has been borrowed on Four per Cent. Debenture stock. Up to December 31st last a total of £1,428,208 has been expended, representing £155,200 per mile of railway in operation.

The accounts indicate a satisfactory maintenance of the steady progress which has characterised the working of the line hitherto. Both the train mileage and the number of passengers carried have increased, the latter by about 3¾ per cent., as compared with the corresponding half-year in 1897. The revenue per passenger has remained constant at 1·91d., but per train mile has risen 0·68d. An almost corresponding rise has taken place in the expenses per train mile, which have grown from 15·66d. to 15·88d. It may be noticed that the revenue and expenditure per mile of line have substantially risen, and that the various items of the latter have remained very constant.

The following table is interesting as showing the increase in the traffic since the line was opened :—

Half-year ended	No. of passengers* carried.	Receipts.†	Ratio of expenditure to total revenue.	Per cent dividend.	
				Pref.	Ord.
Dec 31, 1890 (11 days)	165,000	£1,568	...	...	...
June 30, 1891	2,412,343	19,403	79%	5	...
Dec. 31, 1891	2,749,055	19,799	76%	5	...
June 30, 1892	2,813,162	20,931	70%	5	⅛
Dec. 31, 1892	3,117,602	22,003	67·9%	5	⅝
June 30, 1893	3,146,656	22,458	64·6%	5	¾
Dec. 31, 1893	3,093,351	22,068	64·6%	5	⅝
June 30, 1894	3,383,154	23,565	61·7%	5	1
Dec. 31, 1894	3,275,649	23,541	60·9%	5	1¼
June 30, 1895	3,113,199	23,711	61·6%	5	1⅛
Dec. 31, 1895	3,172,438	23,780	59·6%	5	1¼
June 30, 1996	3,192,672	24,022	60·0%	5	1⅜
Dec. 31, 1896	3,368,480	25,456	56·8%	5	1¾
June 30, 1897	3,437,810	26,403	57·6%	5	2
Dec. 31, 1897	3,337,861	25,473	56·7%	5	1¾
June 30, 1898	3,478,977	26,357	56·7%	5	2¼
Dec. 31, 1898	3,462,814	26,320	56·2%	5	2

* Exclusive of season ticket holders.

Out of the £12,090 working profit for the half-year, £2,905 has been paid in interest, and the surplus, with £1,005

Digitized by Google

balance from the immediately preceding half-year, has afforded a dividend on the Ordinary shares of 2 per cent. after meeting the 5 per cent. dividend on the Preference shares.

Considering the fine weather which characterised the latter part of last year, the above results are very satisfactory. Both tunnels of the extension from the Borough to Moorgate-street station, and also the subway to the Central London Railway, are completed, while the three stations are almost finished. It is anticipated that the extension from Stockwell to Clapham Common will be completed for traffic early next autumn. The generating station at Stockwell is being extended by the erection of a new boiler and engine house which will be ready for the machinery this month. It will be noticed that the rolling stock has been increased by the addition of three locomotives. Thirty additional coaches also are being delivered.

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to "The Electrician" Printing and Publishing Company, Limited, and be crossed "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.

"The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" commence in April and October.

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 0d.	16s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" Printing and Publishing Company, Limited. The well-known "Electrician" Series of Standard Electrical Works at present consists of—

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Trembley Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particular on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I.** Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 92 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 8d., post free, 8½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

NOTICE.—GOOD FRIDAY WEEK.

"THE ELECTRICIAN" will be published on THURSDAY in Good Friday week instead of on Friday. Communications intended for this issue must reach us not later than Wednesday morning's post.

Alterations to existing Advertisements and Copy for new Advertisements should reach the Publisher on Tuesday, but in any case not later than Wednesday morning.

MUNICIPAL ELECTRIC SUPPLY BUSINESS.

There lies before us a document purporting to be a return, to the order of the House of Commons, "of the water, gas, tramway, electric lighting and other reproductive undertakings carried on by municipal boroughs" in England and Wales. The return bears the date March 6, 1899, and embodies financial statistics covering a period of five years ended March 31, 1898. Ostensibly it represents the capital invested in, and the amount of business, profit and loss involved by, municipal trading undertakings in the two countries named, no regard being paid to similar undertakings in Scotland and Ireland. A document of this description, provided it were drawn up in an impartial spirit, and were both accurate and complete, would afford means for reliable judgment to be arrived at as to the commercial characteristics of municipal trading. It would not only indicate the precise allocation of capital to the various departments of such trade, *e.g.*, electric lighting and tramways, but would also be a valuable guide in comparing municipal undertakings of any description with similar undertakings worked by private or joint stock enterprise. At the present moment, therefore, this document should come quite opportunely, when throughout the land and in our legislative assembly the question of municipal trading is being actively discussed.

The undertakings classified under various heads and embodied in this return comprise waterworks, gasworks, tramways, electric lighting, markets, baths, &c., cemeteries, working-class dwellings, piers, &c., and a miscellaneous collection not specified. Harbours, public libraries, and some few other species of trading undertakings are, however, not included. The "total capital, inclusive of borrowed capital," provided by the municipal authorities, amounted at the date specified to £88,152,595. We believe that the aggregate

Digitized by Google

local debt for England and Wales at the beginning of last year was approximately 260 millions sterling; so that the capital invested in trading works represents about 34 per cent., or slightly over one-third of the total municipal debt. As a matter of fact, however, the proportion is very much in excess of this, for the enlightened compilers of the return before us appear to have been oblivious of the fact that such a place as London is in existence, or else they have been content to regard the undertakings of metropolitan vestries as not coming into the category of works "carried on by municipal boroughs." At any rate, London is completely ignored. Taking the return as it stands, however, we note that the total capital borrowed was £83,379,931, of which £11,720,904 had been repaid, leaving £71,883,232 as the outstanding debt. The aggregate accumulated sinking fund stood at £3,203,597. So much for the capital account: let us now consider the business done. During the five years ended March 31st last the average aggregate annual income was £8,898,376, representing a turn-over of about 10 per cent. of the total capital. The average annual "working expenses" are set down at £5,819,597, so that the item designated as the "average net profit" is given as £3,613,668. This last item represents 4 per cent. of the capital, and we might almost have been persuaded by this item to believe in the lucrativeness of municipal trading, were it not that closer inspection revealed that what is termed the "average net profit" is far from representing money wholly available for expropriation to purposes outside the requirements of the business. It is not exactly what a business firm or company would regard as money available for distribution as dividends. To begin with, practically the whole of the so-called net profit, viz., a sum of £3,127,271, has been paid away as interest on borrowed capital, and in repayment of capital; and out of the residuum only the paltry sum of £81,167—less than one-tenth per cent. on the total capital—has been set aside for depreciation of property. Thus the clear profit on the combined efforts of the municipalities during the past five years is only some £400,000 per annum—less than ½ per cent. on the capital invested. Assuredly the debate as to what should be done with municipal profits need not yet grow heated; a starving depreciation fund implores the sympathy of the disputants, and can absorb all the profits and much more before it will be over-fed.

Sufficient has been said to reveal both the general scope of this Parliamentary return and the general trend of municipal trading. Let us now consider in greater detail the one item in the return which possesses especial interest for electrical engineers, viz., "Electric Lighting." The "summary," from which our foregoing quotations have been made, sets forth that the total capital invested, on March 31st last, in municipal electric lighting undertakings in England and Wales was £3,416,711. As, however, London has been ignored, this excludes the considerable capital acquired by the metropolitan vestries, and some £485,500 should therefore be added to the total. It is next stated that the capital actually borrowed was £3,108,533, of which only £108,848 has been repaid, leaving a balance of £2,990,582 yet to be repaid. It appears that the aggregate sinking fund stood at £101,642. Examination of the detailed tabular statement which follows the summary reveals that only 55 electric supply undertakings have been considered; but the omissions, excepting those in London, are of trifling importance. Proceeding with the summary, we find that the "average annual income" during the past five years was £304,499, or 9 per cent. on the capital. Out of this £168,755 was spent in "working expenses," leaving £137,320, or 4 per cent. on the capital, as the sum representing what the compilers of the return are pleased to call net profit. Considering, however, that no less than £126,659 has been paid out in interest and repayment of loans, and that the poor little sum of £3,747 has been dignified with the chilly distinction of being made into a depreciation fund, it is evident that there has been precious little real profit-making. Add £126,659 to £3,747, and substract from £137,320, and you get the item £6,914 as the average annual real profit of municipal electric supply during the five years ending March 31st last. It represents the magnificent return of just ½ per cent. on the capital invested. No doubt we shall be told that municipal authorities despise profits and all the sordid things beloved of mere money-making companies. Be that as it may, it is at least to be expected of municipal works that they should be run with a clear balance-sheet. Examination of the return shows that in the majority of such works this requirement is not realised. Of the 55 electrical undertakings considered, 44 are said to have made a net profit, but we find that there were no less than 49 concerns for which for five years nothing had been set aside for depreciation. Further, it is evident that the six concerns which had had regard to depreciation had only mustered £3,747 between them, not more than $\frac{1}{10}$ per cent. on the capital. We may go still further, and discover that although 44 undertakings are stated to have made a net profit averaged over five years, only 19 have been able to pay interest and repay loans without drawing upon the District Rates, or some other outside source. Indeed, it is evident all through the return that it is the good management of a few large undertakings, such as those at Brighton, Manchester and Liverpool, and not an all-round or fairly general success, that has imparted to the return the semblance of satisfactory results which is so apt to be the most illusory feature of statistical documents on municipal trading. The good deeds of the few are treated as works of supererogation that can cover the sins of the multitude. This principle of ethics cannot be admitted, at any rate, to apply to municipal or any other form of trading.

REVIEWS.

The Free Expansion of Gases. By J. S. Ames, Ph.D. (London and New York: Harper Bros. 1898.)

This little treatise forms one of Harper's series of Scientific Memoirs, and embodies memoirs by Guy-Lussac, Joule and Thomson (Kelvin). The translating and editing have been undertaken by Dr. Ames, who is editor of the series. The work presents in a compact form, and one easy of reference by students of physics, the general mathematical treatment of the physics of the expansion of gases. It is illustrated with diagrams that serve to elucidate the text, rather than with mere pictures, and the book throughout is equipped with a number of valuable tables of constants and other physical quantities relating to the thermodynamics of gases.

Prismatic and Diffraction Spectra. By J. S. Ames, Ph.D. (London and New York: Harper Bros. 1898.)

This is another of Harper's Scientific Memoirs, and embodies the memoirs of Joseph von Fraunhofer, famous as the discoverer of the transverse lines in the luminous spectrum. The book is uniform with the one referred to in the previous review, and gives an admirable and succinct account of the investigations in radiation and absorption lines. The work includes a translation of a Paper giving a short account of the results of new experiments by Fraunhofer on "The Laws of Light and their Theory," this Paper having been read in 1823, besides a quantity of other literary contributions from Fraunhofer's pen.

ELECTRIC TRACTION AND ITS APPLICATION TO SUBURBAN AND METROPOLITAN RAILWAYS.*

BY PHILIP DAWSON.

There is no longer room for doubt that electricity is the one pre-eminently successful motive power for tramways. This is proved by the rapid growth of electric traction. The words "experimental line" have fallen out of use, yet it is only a few years ago that those who ventured to foretell that the trolley system would be generally introduced into this country were ridiculed. There is no country in which electric traction is advancing more rapidly, and in which finer plants are being installed than in Great Britain. The day is not far off when horses and steam will have disappeared from the streets as far as tramways are concerned, and when the horse 'bus as a competitor will be no longer known. The problem of greatest importance, however, in which electric traction will be a principal factor, is the rapid transportation of large crowds from and to their business in our cities. The object of this Paper is to investigate in a general way the special requirements of this service, and to demonstrate the special adaptability of electric traction to it.

It is evident that the only solution of rapid transit lies in railways, which must be either overhead or underground, and of both London possesses a greater mileage than any other town in the world. The factor of initial expenditure must restrict the number of tracks available for the up and down traffic. The stopping places on such lines must of necessity not be far apart, and to diminish the crowds on the platforms and to increase the number of passengers the trains must follow each other with the greatest possible frequency. Consequently, the average speed of the trains must be increased as much as possible without unduly diminishing the distance between two consecutive trains, which would be dangerous. Steam locomotives have probably reached their approximate maximum development, and the results so far obtained with them for the class of traffic in question are far from satisfactory. They do not get up speed rapidly, owing chiefly to the torque on the driving axles constantly varying in consequence of the reciprocating motion of the pistons. They are not economical as their fuel consumption is practically the same whether they are exerting their fullest power, coasting or standing still, and their maintenance is very costly.

There is a commercial limit as far as distance is concerned beyond which transmitting power electrically will not pay. But that limit varies with each case, and cannot be ascertained except by the most careful calculation after all the conditions that maintain have been minutely examined. England was the first country to introduce electric traction on railways, both underground and overhead, as instanced by the City and South London, and Liverpool overhead electric railways. But, to prove commercially that very much heavier traffic could be handled, that much greater distances could be traversed, and to develop on a large scale the necessary machinery was again left to America, and hence the necessity of being practically confined to American experience and examples in this Paper. There are practically three methods of handling electrically the traffic on a railway, namely:—1. By locomotives or motor cars hauling a train of trailer cars. (2) By independent motor cars. (3) By a set of independent motor cars formed into a train and handled from the front car or from a so-called controller car. Each car, however, can be separated from the train, and then becomes an independent motor car. As regards the supply of the necessary current for the motors, there are three distinct methods:—Firstly, by accumulators or storage batteries which may be carried either on the motor car or locomotive, or on a tender. Secondly, by having a car containing a stationary engine, dynamo and boiler, which supplies the necessary current to the motors on the cars comprising the train of which it is part, and as proposed by W. Heilmann. Thirdly, by continuous or multiphase current supplied directly from a generating station or from a sub-station which, in its turn, gets its supply of energy from the main station, the current being distributed either in the form of direct or polyphase to conductors running along the lines, and from which the power is supplied through sliding contacts on the cars to the motors. The two former methods, as far as this Paper is concerned, will not be discussed, as sufficient data are not available to justify their being considered. The system of transmission of energy to the motors by means of conductors laid along the track, will, therefore, alone be considered. This method allows of several variations as far as the generation and distribution of power is concerned, amongst which the chief may be set down as follows:—(*a*) One continuous current generating station supplying current direct to contact rail. Where drop in pressure owing to distance becomes excessive, a negative "booster" may be used—it serves, so to speak, to pump back the current to the station, and is self-regulating, not taking at any period more power than is actually required to pump the current back. Should there be one or two lines too long to enable them to be worked this way, polyphase high tension generators should supply the power to one or more sub-stations along the line, as may be found necessary, in which rotary converters are located, which transform the current back into continuous. The polyphase generators to be driven by continuous current motors in the generating station. As an example of such a station, the new Dublin tramway power house may be taken. (*b*) One central station generating continuous current with sub-stations in which accumulators are located along the road, and which are charged by means of a booster and special cables. As an example of this system, the Leeds tramways may be taken as designed by, and carried out by, the late lamented Dr. John Hopkinson. (*c*) A series of stations, as described under (*a*) and (*b*), situated at various distances and connected together one with the other. As an example of this, the tramways and light railways in and round Boston, Mass, may be taken, owned by the Boston Elevated Railway Company, which has absorbed the well-known West End Company.

Data of Boston Elevated Railway.

Track miles operated	305
Number of cars	2,648
Car miles run during 1898	29,787,000
Passengers carried during 1898	172,764,300
Number of power stations	5
Total capacity of power stations in kilowatts	16,100
Total rated indicated horse power of engines	24,000

(*d*) A power station generating polyphase currents, which, by means of static step-up transformers, are transmitted at tensions which run from 2,500 to 40,000 volts to sub-stations where static step-down transformers reduce them to pressures of 300 to 350 volts, the current at this pressure enters rotary transformers, which deliver direct current at 500 to 550 volts to the line. As an example of this later system, the Central London Railway, which is now under construction, may be mentioned. (*e*) A three-wire system with continuous current, the rails or return forming the neutral wire. This has been tried and found wanting, and the engineers of the Central London Railway most carefully investigated its possibility and decided in favour of polyphase transmission and rotary converters, and rightly so. From careful calculations and the investigation of what has been done both in Europe and America, there is no getting behind the fact that for any power station which will exceed 4,000 kilowatts in capacity, the polyphase system is nearly certain to prove commercially the only admissible one. This statement is upheld by such an authority as Mr. H. F. Parshall, M.I.C.E. It is evident that in the particular cases at present under consideration (suburban and metropolitan communication), more than 4,000 kilowatts will be under consideration, and therefore nothing, as far as the power station and transmission is concerned, but polyphase currents will be considered.

There are two distinct varieties of service to be catered for. One that on a system like the Metropolitan and District, where the stops are frequent and the runs short. The other the case of long distance lines with few stops. In the present Paper it is only proposed to consider the first variety. In this case the use of polyphase motors need not be considered, as for work entailing frequent stopping and starting they have not up to date proved satisfactory.

A short examination of the importance of rapid acceleration on lines having stopping places at short intervals is interesting. Practical experience with electrically-driven motor cars, or locomotives, on the experimental track of the General Electric Co., at Schenectady, has proved that it is perfectly feasible to attain a speed of 30 miles an hour 10sec. after starting from a standstill. Assuming a level track, and that during 65sec. the current is cut off, and the train allowed to coast, that the brakes are then put on, the train will be brought to a standstill 15sec. later, and the total time from start to stop will be 90sec. Under these conditions it will be found that the average speed will have been 23·16 miles an hour, and that the total distance run will be about 0·55 of a mile. Assuming that instead of attaining the 30 miles an hour in 10sec., it took 30sec., and that this full speed of 30 miles an hour was kept up for 40sec. longer, and the brakes then put on, the train would be brought to a standstill in 90sec., and the average speed would work out as 21·66 miles an hour, or an average speed of about 10 per cent. less than in the previous case, the consumption of power, however, being much greater. It is evident that the most important point is to attain a high average speed, and to keep the maximum speed attained as low as possible, as by so doing less power is required in braking the train, and also less power is required to run the train. The time between the moment when the maximum speed is attained, and when the brakes are put on, should be at least from four to six times that required for stopping the train, so as to allow for errors in judgment on the part of the driver, and also to enable him to make up lost time. On the Manhattan Elevated Railway, in New York, the trains which are drawn by steam locomotives take 20

seconds to attain a speed of 14 miles an hour, or less than half the speed in double the time as compared with electric traction just mentioned. A much larger current will be required to attain a rapid acceleration than to obtain a slow one, but the current will be required during a much shorter time, and the total energy supplied will be less in the case of rapid than of slow acceleration. This fact must not be lost sight of when calculating the feeders for such a system, and the train service should be arranged in such a way that as few trains as possible start together. Furthermore, the more rapid the acceleration required the larger will the motors have to be, and, therefore, there will be a limit, above which it will not be advantageous to push the rapidity of acceleration. In new tunnel lines, such as are now being constructed all over London, it will be evident that it is an advantage to have the stations built with a down grade for the trains to start, so as to help the motors and reduce the current required at starting; and that, similarly, it will be an advantage to have an up grade when nearing a station, so as to reduce the amount of power required in braking. By properly choosing these gradients it is found that a total economy of from 40 to 50 per cent. in the total power required by a train may be made. According to Mr. Potter's tests, it was found that, during acceleration, an average power of 32 amperes per ton of weight of train was required.

With a complete train composed of one motor car and two passenger cars, weighing complete 148,000lb., a maximum horizontal effort of 9,750lb. was required in acceleration, the maximum current was 780 amperes at 500 volts, the maximum speed attained was 32 miles an hour, and the time taken to attain the speed was 34sec., the motor car being equipped with two 200 H.P. motors.

In another case, with a train composed of one motor car, equipped with two 125 H.P. motors and one trailer car, total weight of train being 103,000lb., a maximum speed of 31 miles an hour was attained in 37 seconds, the maximum current being 500 amperes, and the maximum horizontal effort required to attain acceleration 5,640lb. In a series of tests made on the Nantasket Beach line it was found that with a heavy motor car, 51ft. in length overall, carrying 100 passengers, weighing 31 tons, on an average distance of 2,980ft. between stations, a maximum speed of 40 miles an hour was attained, the average speed being 18 miles per hour, and the power required was 0·098 Board of Trade units per ton mile. In an experiment with a train composed of one motor car and one trailer car, weighing 57 tons, with an average distance between stations of 4,280ft., a maximum speed of 37 miles was attained, the average speed being 17 miles an hour, the power required being 0·067 Board of Trade units per ton mile.

From a comparison of the actual results obtained on the elevated electric railways of Chicago and on the Metropolitan and District line in London, we see that whereas the maximum speed of 25 miles an hour is obtained in 10 seconds with electric traction, it takes 33 seconds to do it with steam locomotives—and that whilst the electrically propelled train could do the distance of 1,880ft. in 66 seconds, with steam it would take 93 seconds, or nearly half as much time again. If in the case of electric traction the power is cut off the moment the maximum speed of 25 miles an hour is obtained, and the train allowed to coast before the brakes are put on, the distance considered would be done in 76 seconds, and that the steam driven train even then would take more than 25 per cent. more time to do the same distance.

CORRESPONDENCE.

THE THEORY OF THE MARCONI TELEGRAPH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having had the pleasure of attending both meetings in connection with Mr. Marconi's paper on Wireless Telegraphy I, in common doubtless with many others, was struck by the entire absence of any attempt on the part of Mr. Marconi to afford his listeners any theoretical explanation of his system of signalling through space. It seems to me that this is a great omission, and must tend to place Mr. Marconi at a disadvantage, which he should at once rectify by availing himself of your columns to give us now what we are entitled to. Should he fail to do so I trust that some of your correspondents will step into the breach and take up the position which ought to have been occupied by Mr. Marconi. The interesting messages quoted by him in his Paper are a sufficient proof of the practicability of conductionless telegraphy, and should satisfy all concerned that it possesses a certain commercial value; but this is not enough for those interested in the scientific aspect of the question, and who have so long and patiently waited to hear Mr. Marconi expound the laws which underlie the results obtained. So far, such information as we have gained on these points has come from others rather than from Mr. Marconi himself, and, under the circumstances, this is a sufficiently singular fact.—Yours, &c.,

CONDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: From your leader on "Wireless Telegraphy," in this week's *Electrician*, it appears that you have quite misunderstood my remarks.

I did not propose a theory of discharge from given points, as you suggest, but merely gave the points on an electrical machine as an illustration of the fact, that on a charged conductor the electric force is greater near the convex parts than near the flat or concave surface.

I did not imply that there was any discharge from the wire, but only that the displacement current in the ether must be greater the further the given portion of the wire is from the earth.—Yours, &c.,

J. ERSKINE-MURRAY.

Poole, March 21, 1899.

THE WEHNELT INTERRUPTER.

TO THE EDITOR OF THE ELECTRICIAN.

The new Wehnelt interrupter for induction coils would suggest the search after a mechanical method of arriving at a high rate of interruption of current, without risk of burning the contacts, notably, as is the case when *one* terminal alone is constantly in circuit (by the magnetic make and break).

The following idea is proposed with some diffidence; as it would probably—if of practical value—have been suggested by others: but it is this:—

Could not a wheel be constructed—driven by a separate current, if desired—consisting of a convenient number of sectors, insulated from each other near the periphery, but connected at the axis. A brush (or, perhaps, pulley revolving) or other convenient arrangement for ensuring a sliding contact, would glide over the surface of the revolving wheel or disc, near or on its periphery.* The rest is sufficiently obvious. One terminal of the exciting battery would be connected with the axis of the wheel, the brush would be connected through the primary of the induction coil to the other terminal of the battery. A condenser could, of course, be inserted at will, and would at least diminish the sparking, if found otherwise not without advantage.

The object of the idea is naturally to do away with the evil of *one* terminal alone as interrupting mechanism (with attendant heating), and to secure full control of rate of breaking current—by varying at option speed of wheel—results which are very imperfectly attained with the Wehnelt, or with the mercurial make and break mechanism. Your readers may judge what value (if any) the above suggestion may possess, if you think it well to accord this a place in *The Electrician*.

Hamburg, March 21, 1899. S. TOLVER PRESTON.

* The brush could, by a screw, be made to vary the position of contact on the revolving disc, at will—if thought advantageous.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Perhaps the following may be new to some others who are using Dr. Wehnelt's interrupter. In experimenting I connected the interrupter with the 100 volt circuit without any coil. It then refused to work, one bubble just being off at the moment of making contact.

Further experimenting shows that self-induction is required to make the brake work. Perhaps the action is in this wise. On the current being switched on, the positive pole is immediately afterwards insulated by a layer of oxide and the current ceases. The counter current induced in the coil can then act, and for a moment converts the positive pole into a negative one, absorbing the oxide and setting free a little hydrogen, and so the action goes on.

That this is the case I found by collecting the gas given off from the "positive" pole and applying a light, when there was a brisk explosion, leaving, however, a considerable amount of oxygen and ozone in the tube.—Yours, &c., ALEX. HILL.

THE NERNST ELECTRIC LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I notice from the abstract of the discussion on Mr. Swinburne's Paper, given in your issue of Feb. 24, that Prof. Ayrton did me the honour to refer to views which I have held for a number of years regarding the source of light in the Welsbach mantle, and I may say also in the calcium light. I thought that it might interest some of your readers to have a more explicit statement of what these views have been, and still are, and I enclose a statement [subjoined], which is being sent to the *Electrical Review*, New York, at the request of its editor.—Yours, &c., ELIHU THOMSON.

Lynn, Mass., March 10, 1899.

STATEMENT.

Some six or seven years ago, when the Welsbach burner first came into prominence, I made some experimental tests, which convinced me that the light of the burner was not merely due to the material being brought to a high temperature by the hot gases of the flame, and the experiments also convinced me that the material of the burner itself did not possess any peculiar property of luminescence, except under specific conditions of use. I may say that these views have been freely communicated to my associates and others ever since I first held them.

I found that the material, when introduced into the flame of an arc and very highly heated, did not shine with any greater light than a piece of carbon filament would under similar conditions, and it appeared to me that what was necessary to develop the light-giving quality was to immerse the material of the mantle in gases undergoing conbustion, *i.e.*, in gases containing combustible and free oxygen. This was illustrated by the use of an ordinary blow-pipe flame; when a piece of a mantle was placed in the reducing flame it glowed brightly, but when carried out to the point of the flame (where the combustion was completed) it glowed far more faintly, though the temperature of the gases was doubtless as high in one case as in the other.

This led me to make other experiments, which, in general, confirmed the view here expressed: that the light given out by a Welsbach mantle is, in my opinion, largely due to union of the gases taking place within the pores. Gases may possibly be condensed within the pores, and there caused to unite, producing high temperatures; or the material of the mantle itself may be intermediary in a set of chemical changes, which result in the oxidization of the carbon and hydrogen of the flame.

It is interesting to note in this particular that the calcium light in which a jet of oxygen and hydrogen, or hydrocarbon gas, is projected upon a piece of lime, probably embodies the same principle of action. Frequently, in working with the calcium light many years ago, I have been struck with the

Digitized by Google

great difference between the amount of light given out by the lime when the tip of the hydrogen flame only reached the lime after the combustion was fairly complete, as compared with that given out when the lime was, so to speak, pushed right into the flame where active combustion was taking place. In the former case there was but little emission of light, and in the latter a light of great brilliancy was evolved.

It is well known that a properly adjusted calcium light represents a high luminosity and intense light emission for the small spot of lime heated. It is also well known that at that spot the character of the lime undergoes a change. It is gradually volatilised or eaten away just as the material of the Welsbach mantle is gradually carried off. This is noticed especially at those parts exposed to the flame in its most intensely active zone of combustion.

I have never been a believer in any special luminesence idea in connection with the mantle constituents, and it is a source of some satisfaction to me that views akin to those I have held for so long a time appear to be gradually gaining ground. (Signed) ELIHU THOMSON.

PARLIAMENTARY INTELLIGENCE.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT CO.'S BILL.

The Select Committee which is considering the group of Bills dealing with the supply of electricity to London resumed, on the 17th inst., the consideration of the Bill of the St. James's and Pall Mall Electric Light Co. The opposition of the Vestry of St. James's, Westminster, was opened by Mr. Freeman.

Mr. HENRY MONSON, Surveyor to the Vestry, said that when coals were being unloaded at the works of the promoters in Carnaby-street the thoroughfare was blocked. There was a clause in the Bill, which said that not more than 20 houses inhabited by working classes should be taken, but 40 tenements would be acquired.

The CHAIRMAN asked if there were any precedents in which, in a case like this, it had been decided that more than 20 houses were being taken.

Lord R. CECIL: There is no decision given to that effect. The ordinary rule of Parliament has been to have a clause in these Bills forbidding more than 20 houses belonging to the working classes being taken away without the consent of the Home Office. The petitioners desire the promoters to insert a penalty, the effect of which will be, not only to forbid us from taking 20 houses, but to render us liable to a fine of £500 if we do take them. That we have put into the filled-up Bill. We submit that the Home Office is the proper authority to raise this point if anybody is.

A MEMBER OF THE COMMITTEE: Are the promoters prepared to make a proposal for rehousing the 340 people who will be dispossessed?

Lord R. CECIL: We say that that is a delusive number. The question is not the number of persons who will be disturbed, but the number of persons of the working classes. It includes people employed in our own works.

WITNESS denied that the present works had improved the neighbourhood; noxious smells and heat came from the works. They had received complaints of the Company's works from householders.

By Lord R. CECIL: Has not the street become more respectable since the Company came there?—The particular street in which the works are situate is more respectable.

The CHAIRMAN: Has the rateable value of the neighourhood gone down?

WITNESS: Well, I do not put it in that light ——.

I understood you to say that this new station would reduce the rateable value of the surrounding property. Has the present building had that effect?—What I say is that the works will have that effect. I take as the foundation of that statement the complaints made as to the nuisance in Mason's-yard.

Tell us about Ganton-street. Has the rateable value of the property been reduced since the present station has been built?—I don't think it has, but I think it is likely to decrease.

Dr. JAMES EVANS, Medical Officer of Health for St. James's, said complaints had been made as to the smoke and cinders discharged from the chimney of the works in Mason's-yard. This was due to the chimney being overworked.

Other evidence was given as to noise and vibration.

Mr. RUSSELL, Q.C., addressed the Committee in support of the Craven Trustees' petition. The trustees, as owners of the land which was proposed to be taken, and of property surrounding it on three sides, protested against being deprived of their property, and said that if the Bill were passed care should be taken to provide for their adequate compensation. He submitted that the promoters were present, not in the public interest, but for their own benefit as a commercial undertaking. Their desire was to prevent another electrical company with whom they were in competition from having an advantage over them between now and the time when the works under the next Bill—the Central Electric Supply Bill—would be constructed.

Sir JOHN WHITTAKER ELLIS, as an expert surveyor and valuer, gave evidence against the Bill, and expressed the opinion that the effect of the construction of the proposed works would be to drive out of the district a large number of the inhabitants. Large factories always had that effect. To his mind, both for the sake of preventing a nuisance and avoiding the dispersal of the population, it would be wisest for the promoters to go into the suburbs to establish their new works. The electric light companies should do what the gas companies had had to do. It was said that the Lands Clauses Acts would give the petitioners the compensation to which they were entitled, but it was difficult to say whether adequate compensation would be given.

Mr. BOYLE, Q.C., then addressed the Committee for the remaining petitioners.

Mr. BALFOUR BROWNE summed up the case for the promoters. He submitted that being at Carnaby-street with the authority of Parliament, and having a large amount of plant there, and, further, being in want of an increased supply of electricity, it was only right that they should be allowed to so extend their works as to give them all the energy they required pending the construction of the proposed new works on the Regent's Canal. They were only proposing at Carnaby-street an extension sufficient to last them up to 1901. They only desired to have 2,500 H.P. in addition to the 4,500 they possessed at present. The Bill was really in the interests of the public, who had a right to be supplied with what electricity they required. With regard to the evidence as to the nuisance he held that the petitioners should be left to the remedy afforded by the general law in regard to the Carnaby-street works, present or future. If a nuisance were created and property were injured thereby the question would be how much compensation should be paid.

The Committee remained for a short time in deliberation, and the CHAIRMAN said they had decided to pass the preamble subject to the condition that Ganton-street should be widened. This would apply to that part of the street on which the new works would abut. As to the existing works the question would remain open and in the meantime the Committee would visit the station.

The Select Committee of the House of Commons engaged in considering the scheme of the St. James's and Pall Mall Electric Light Co., for the extension of their works, met again on Monday. As previously announced, the preamble of the measure was passed.

Several clauses were now brought up on behalf of the St. James's Vestry, one to effect the payment of rates in respect of the new site during the progress of works.

Lord R. CECIL objected to this clause being considered, as no condition of the kind had been laid down in the decision of the Committee.

The Committee declined to insert in the Bill a new clause proposed by Mr. BERKELEY, with regard to the repairing of a sewer, which would be interfered with by the proposed new works; Lord ROBERT CECIL pointing out that there was nothing in the Bill which would give the promoters power to interfere with the sewer in question.

A new clause was proposed to prevent the promoters from damaging the roadway adjacent to the new works during their construction, or to require compensation to be made for such damage. This clause also the Committee declined to accept, holding that the Company were entitled to use the roads for their traffic, and that any wrong doing on their part would be met by the ordinary law.

A clause was agreed to, providing that the works in Ganton-street, whilst they were in progress, should not be left in "an unsightly condition."

The Committee refused to insert a clause giving power to the Vestry to regulate the traffic of the Company. They considered that the regulation of the traffic should rest with the police.

A new clause, submitted by the Vestry, dealing with the displacement of the working classes and the provision in the Bill which stated that not more than 20 houses should be demolished, was rejected by the Committee on the ground that the Home Office already possessed sufficient power to deal with this matter. In like manner clauses dealing with the question of the committal of nuisances by the promoters at their works were rejected on the ground that the ordinary law was sufficiently strong to cover the point.

A clause providing for the widening of Ganton-street was submitted and approved.

THE CENTRAL ELECTRIC SUPPLY BILL.

The same Committee as had been discussing the St. James' and Pall Mall Co.'s Bill considered this Bill.

The counsel engaged were: For the promoters, Mr. Balfour Browne, Q.C., Mr. Pember, Q.C., Mr. R. Wallace, Q.C., and Lord Robert Cecil; for the Metropolitan Electric Supply Co., Mr. J. D. Fitzgerald, Q.C., and Mr. Moone; for the London County Council, Mr. Worsley Taylor, Q.C., and Mr. Du Cane; and for the Marylebone Vestry, Mr. Talbot.

Mr. BALFOUR BROWNE said the object of the Bill was to confer on the Central Electric Supply Co. (Limited) power to construct works and supply electrical energy, &c. It was lucky, he said, that the Bill had been referred to this Committee, because in the inquiry which had just taken place they had heard a good deal about the present proposal. The principle of the measure was one which was inquired into and reported upon by the Joint Committee of last year. He was sorry to see that a considerable number of the petitioners—amongst the others, the London County Council and the Vestry of Marylebone—absolutely ignored that report altogether, and raised arguments which were in place before that Committee, and which were put before it, but which, now that the Committee had reported, seemed to him to be entirely out of place. The promoters were proposing to make a new generating station in the parish of Marylebone, close to the Regent's Canal and the Central London Railway. They were proposing to go outside their own district. The promoters were the St. James's and Pall Mall Electric Lighting Co. and the Westminster Electric Supply Corporation. The time would rapidly come when the capacity of the two existing generating stations of the former Company would be exhausted. These two companies were combining to go outside their districts to make the proposed works on the Regent's Canal—in a most suitable

Digitized by Google

position, in accordance with the report of the Joint Committee of last year. To connect the Company's works with the proposed station, they would have to lay trunk lines through the streets, and the breaking up of streets was also in conformity with the report of the Committee. These were the two principles which he was here to propound and which were reported on in his favour in the report of the Joint Committee. Of course, the companies would still be open to action if they conducted their works without due care, and the companies were bound to give the same notices and *locus standi* to the local authority in the district in which the new works would be constructed as though they were in the area of supply. The promotors were giving the Marylebone Vestry power to dictate the route which should be followed by the companies' wires. The Vestry asked for power to purchase the works, but they would not supply the Marylebone district, and such a proposal had never been contemplated in the Act of Parliament. If the petitioners were to receive power to buy the works it might enable them to supply not only their own district but half London. The promoters were ready to supply electricity in bulk to a large number of authorities far beyond Marylebone. The promoters wished to be near the Regent's Canal with their new works, to be near the railway, and to have access to the canal to obtain water for condensing. The Westminster Company supplied Hanover-square and adjoining districts, including the Houses of Parliament. The proposed capital would be guaranteed by the two companies, and each would be entitled to take a supply of electricity from the new works. The two companies would receive their supply of current at cost price so long as they took equal amounts, but if one company wanted more than the other it would have to pay a sum sufficient to cover cost and capital. The Westminster Company was started in 1890, had 4,700 consumers, and supplied 350,000 lamps. It had three stations, two of which were nearly at the end of their tether, and the remaining station would be unable to meet the demands upon it after next winter at latest.

Mr. BOULNOIS, M.P., a Director of the Westminster Electric Supply Corporation and of the Central Electric Supply Co., said it was impossible to get a suitable new station in the Westminster district except on most exorbitant terms. There would be no objection to making it clear in the Bill that the promoters would not take power under it to supply electricity to Marylebone.

The CHAIRMAN: If we give you North Bank, which is a public thoroughfare, what would you give the public in return?

WITNESS: We should give them handsome rates. The railway has destroyed the value of the property, I do not think that we can give anything beyond rates.

Prof. A. B. W. KENNEDY gave evidence to show the necessity for extending the sources of supply of electric energy. He denied that the proposed works would be a nuisance to anyone, or would be prejudicial to other companies.

Mr. SYDNEY T. DOBSON (engineer to the St. James' and Pall Mall Company) stated that the generating accommodation of his company was nearly exhausted. The Regent's Canal site had been chosen last year, and would be a very convenient one. Instead of damaging the parish of Marylebone, it would be a great gain to them, as it would give low rates and bring a large number of wage earners into the district. The present rateable value of the property to be acquired was over £3,000. The promoters had not yet settled as to whether the electricity which it was proposed to generate would be continuous or alternating current. If continuous it would be at a high voltage. The combined requirements of the two companies would amount to 18,000 H.P., but power was sought in the Bill to obtain between 40,000 and 45,000 H.P. The cables of the promoters would cross the main transmission main of the Metropolitan Electric Supply Co.

The CHAIRMAN: You stated on the last Bill that at your present works you use Welsh coal. Would you be obliged to use Welsh coal at the proposed new works?

WITNESS: If we can arrange our furnaces so as to avoid committing a nuisance from smoke and dirt it is probable that we should use a cheaper coal. This would probably save us 3s. or 4s. per ton.

You propose to use triple-expansion engines at high pressure? Yes; and so save a great deal in the matter of coal.

So that at these works, in addition to the economy you would effect by using triple-expansion engines, you would also effect a considerable economy in using a cheaper coal, and in having that coal delivered at a cheaper rate on the canal than elsewhere?—Yes.

So that, as a matter of fact, you can produce electricity at the proposed works at a much less cost per unit than you can at either of the works you now have?—Yes.

Sir FREDERICK BRAMWELL, C.E., said he had inspected the proposed site, and considered it extremely suitable for a generating station.

Mr. R. WALLACE, Q.C.: Do you know of cases where lighting supplies are generated in districts which are not served by those supplies?

WITNESS: The Gas Light and Coke Co. and other gas companies.

Do you agree with what was said by the last witness?—Yes; but he omitted to mention the mechanical fire-feeder. If that is used, cheap coal can be used with less risk of creating a nuisance.

This was the case for the promoters.

Mr. WORSLEY TAYLOR, Q.C., for the London County Council, said his clients did not want to prevent this or any other company from extending the facilities they possessed for supplying electric current to the public, but they did want to see that the powers given should be consistent with public policy. The question was whether the Committee would tear up the statutes which at present governed all electric lighting Bills. The Committee, he thought, would hesitate long before they would take on themselves, as a private Bill Committee, doing what should only be done after careful consideration by Parliament. Did they know a case in which Parliament had departed from the practice, namely, that where there were compulsory powers granted to the company, as a *quid pro quo* for that grant there was something put on those who got them in the shape of obligation or regulation or both? The Company, for their own profit were asking for compulsory powers without incurring a single obligation to the public. He objected to the promoters having their Bill without being under the ordinary obligations as to price, inspection, public safety, regulation of works, and so on. Under the general law it was not competent for the promoters to give preferential terms, and they would be bound to give a supply equally to every one in the district. The go-by was given to all these provisions, and two companies, subject to all the conditions of the Acts of 1882 and 1888, would be able to get to a great extent out of them by this joint measure. He asked the Committee if they decided that the preamble was proved to insert clauses in the Bill for the protection of the public?

Mr. BENN, L.C.C., said he thought that in any Bill dealing with the supply of electricity in London, especially any measure proposing to supply electricity in bulk, adequate provision should be inserted to enable some local authority to purchase the works at the expiration of a specified time. There should also be provisions in the Bill incorporating the provisions as to price and regulation inserted in ordinary electric lighting Bills under the Acts of 1882 and 1888. His main objection to the Bill was the absence of a clause relating to the obligation to sell to the local authority—if the local authority desired to buy—at the expiration of 42 years.

Assuming nobody has power to purchase the generating station, and assuming that the distributing companies are purchased by the local authority, would not the result be that the station in Marylebone would have no custom?—Yes.

Would not that be an awkward position for the owners of the generating station to be left in?—That would be an argument for the central authority stepping in as purchaser where it is obviously impossible for the local authority to purchase. You have the power to step in, as you have power at the end of 42 years to take away the area of supply.

The local authority would be in the possession of the mains and of the transforming stations, which would be of no value to them?—These things would be of no use without the generating station.

Would not the people in possession of the generating station be at the mercy of the local authority?—I am not so sure of that; at any rate, the danger to the Company would be very small.

You think the London County Council should have the power to purchase for all London?—Oh, no! What we say is, that the local authority, if it thinks it would be advantageous to purchase a generating station outside its area, should have power to do so. Two or more local authorities should have power to do the same thing if they think it desirable.

In reply to further questions, WITNESS said that as to the Board of Trade, Sir Courtenay Boyle before the Electric Energy Committee, had distinctly stated that he thought a purchase clause should be inserted in these electric supply Bills. It would be practically impossible for the local authorities to put up generating stations of their own. Westminster, for instance, would find it as difficult to get a new site in its area of supply as did the Westminster Company.

By the COMMITTEE: He could not say that if the two promoting companies were bought up their interest in the Central Electric Supply Co. would go with their area of supply. That was a question for lawyers. That was the case for the London County Council.

Mr. E. R. MOORE, for the Metropolitan Electric Supply Co., pointed out that his company generated electricity at Willesden, and carried their transmission main through Marylebone and Paddington for the supply of those districts. It was of importance that there should be no interference with that transmission main. The promoters should be prohibited from supplying Marylebone; they should also be prohibited from disturbing the petitioners' mains for the purpose of supplying other than the two promoting companies with electricity; and, finally, the petitioners should be allowed some voice in saying by what route the promoters should lay their mains.

Mr. TALBOT, Q.C., for the Marylebone Vestry, contended that adequate provision should be made for the protection of the rates of the petitioners. He also protested against the proposal to generate electricity for the six other companies (besides the two promoting companies) mentioned in the schedule. Because these works were a nuisance in Westminster and St. James's it was unfair to foist them on Marylebone. Let the Duke of Westminster find another site for generating works; at any rate, let him face the alternative of either doing that or letting his tenants go without the supply of electricity they needed.

Mr. BALFOUR BROWNE, replying for the promoters, likened the new works to an outside reservoir belonging to a water works company. Every drop of water sold from that reservoir would be subject to the terms regulating the area of supply. As to the insertion of regulations with regard to price, and so forth, Mr. Taylor seemed to forget that this Bill was not for the supply of electricity to consumers, it was for the manufacture of electricity at a cheap rate to be sold to the distributing companies. If they did not supply cheaply they would not get customers. As to the question of purchase, which was the gravamen of the case of the petitioners, the subject was fully considered last year, both by the Electrical Energy Committee and the Committee on the Metropolitan Electrical Supply Co. The London County Council had no power to purchase electrical works. It was true that they had passed a resolution in favour of such purchase, but the passing of a resolution did not give legislative powers.

The CHAIRMAN: The preamble is proved. With regard to Mr. Worsley Taylor's arguments in favour of purchase the Committee do not see their way to depart from the decision arrived at by the two Committees which considered the Bill of last year. The Committee wish to state their view of the large reduction in the cost of production of electrical energy they consider a reduction in price to the consumer should be made from time to time without waiting for the Board of Trade to do so.

Mr. BALFOUR BROWNE: We have done it already by 50 per cent.

Digitized by Google

The CHAIRMAN: The Committee are of opinion that by these improvements the Company will be able to make a still further reduction.

Mr. BALFOUR BROWNE said he hoped they would.

The CHAIRMAN said that some clauses should be drawn to meet the wishes of the Board of Trade.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING BILL.

The same Select Committee dealt with the County of London and Brush Provincial Electric Lighting Co.'s Bill, against which a large number of petitions had been deposited.

Mr. Pember, Q.C., Mr. Balfour Browne, Q.C., Mr. Moon and Mr. Shaw appeared for the Bill; while Mr. F. W. Pember, Mr. Lewis Coward, Mr. Arnold Statham, Mr. Corrie Grant, Mr. Earle, Mr. Dickenson, Mr. Vesey Knox, Mr. Shiress Will, Q.C., the Hon. F. Thesiger, Mr. E. Boyle, Q.C., Mr. Archibald Willis, Mr. Claude Baggallay, Q.C., Mr. A. V. Frere, Mr. Selignan, Mr. Castle, Q.C., Mr. Littler, C.B., Q.C., Mr. G. J. Talbot, Mr. A. G. Rickards, Mr. Pope, Q.C., Mr. Wedderburn, Q.C., Mr. Worsley Taylor, Q.C., Mr. Du Cane, and Mr. Wheeler, Q.C., appeared for the various petitioners. Nor does this galaxy of legal talent exhaust the list. Some of the opponents of the Bill "reserved" counsel, some were represented by Parliamentary agents, and others were unrepresented by counsel.

Mr. PEMBER, Q.C., said the Company's district of supply included a large number of parishes, and they had a very difficult outline or series of outlines to deal with in the way of mains and generating stations. The fewer generating stations a company of this kind could manage to do with the more economically would they be able to supply the large bundle of districts within their area; and it was also essential if the districts were to be supplied in the most economical way that the Company should be able to carry the mains from point to point by as short routes as were practicable. These were two axioms which underlay a proper and effective and economical supply of electricity. The object of the Bill was to enable the Company to purchase additional land for the extension of its generating station at the City-road on the Regent's Canal. They proposed also the extension of their generating station at Wandsworth on the river Wandle, and they asked the Committee to give them power to purchase by compulsion a site for a generating station in the parish of Camberwell on the Surrey Canal. Powers were also sought to enable the promotors to lay mains to connect their various stations with outlying areas of supply through the intervening districts where necessary; and lastly, the promoters proposed to modify the provisions of section 9 of the Electric Lighting Act of 1882 as to the accounts to be rendered by the Company. The Board of Trade could insist that different annual accounts should be kept in relation to every single Order granted. Inasmuch as the Orders granted in the case of this Company were very numerous, covering a large district, it had become a very cumbersome thing to keep separate accounts for them all. A provision was, therefore, inserted in the Bill to obviate this.

The CHAIRMAN asked how long the case was likely to last.

Mr. WORSLEY TAYLOR, Q.C. (for the London County Council), said the Bill was an exceedingly complex one, and there would no doubt be individual points raised, but the petitioners had come to the conclusion that there were certain petitions which involved substantially the same points. They had decided that, saving the right of each individual to go into his own particular case, there should be, substantially, one cross-examination raising points of principle.

Mr. PEMBER, Q.C., continued: The Electrical Energy Committee which sat last year had reported that the proved public advantage of an electrical supply warranted the granting of compulsory powers for the acquisition of sites for generating stations. They had also considered whether a site for a generating station should be given where it was not within the area of supply, and were of opinion that powers for the compulsory acquisition of land for generating stations and of lands or easements for the laying of pipes and so forth in outside districts should be given on condition that the local authority in the district affected had the same rights of petitioning and opposing as though they were the authority over the area of supply, and that similar powers should be given to the authorities through whose districts pipes were laid. Local authorities should have the option of themselves opening up the streets at the undertakers' expense. On the point as to whether compulsory powers should be given in relation to a supply of electricity over numerous districts the Committee reported that such powers should be conferred where sufficient public advantage could be shown in the laying down of plant for high voltage. The promotors of this Bill already had power to supply a great number of districts. Another question the Committee dealt with was whether compulsory powers should be given to local authorities in the district of the generating stations to purchase the works at the end of 42 years. On this point the Committee suggested that the Board of Trade should have power to insert a purchase clause if good cause were shown for such a course. Amongst the main objections to the Bill was that of the County Council, who considered it faulty in containing no clause giving power of purchase to the local authority. The Council seemed unable to learn anything. They quoted the Acts of 1882 and 1888; but those Acts referred to electric lighting, and were passed when electrical energy was little understood. The London County Council were not the authorities to purchase; the local authorities under the Bill being independent of the Council. Another petition declared it was not needful for the promotors to come into the petitioners' district, as the supply to be generated there would be for the use of outside districts. But that was a power dealt with by the Committee of last year in the manner he had pointed out. Whitechapel also petitioned. That district had power to supply electric light, but did not use it.

Mr. TALBOT (for the Whitechapel Board of Works): We are spending money on it.

Mr. PEMBER said the present Bill had evidently galvanised the Board of Works into life. They had gone the length of consulting an engineer, but he should be curious to know what they had spent and how they had spent it. The learned counsel having dealt with the remaining petitions,

Mr. W. H. PREECE said there were now over 30 electric generating stations in London, and if small stations continued to be construted the progress would be so great that the stations would become a nuisance. It was far preferable to supply electricity in bulk from a few central stations scattered on the rivers or on the main lines of railways. The larger the station and the more continuous the output the cheaper would be the cost of electrical energy. The sites proposed, which he had carefully inspected, were admirably fitted for the purpose, and were not likely to prove a nuisance,

If you could keep your plant at full work for 24 hours at what price could you supply electricity?—At 1d. per unit. If in full work for 15 hours the price might be brought down to 2d. At present the plant was only in full work some three hours a day, and the supply could not be given at less than 4½d. per unit. He looked to the Metropolitan Railway Co. using electricity in the future, and also to the London County Council using that motive power for its tramways. There would then be a large current required, and the supply would be obtained in part from some of the proposed works.

If your expectations are realised, what will the cost of electricity be reduced to?—If we assume that the electric light now would be supplied at 4½d. per unit, and if we could from these great central stations secure the supply of current for tramway and electric railway purposes during 12 or 14 hours a day, the cost of electric lighting in London would come down to 3d. per unit, or 2½d.

By Mr. LEWIS COWARD (for the Fulham Vestry): Seeing that Fulham was taking measures to supply electricity itself, it would look like unfair competition for the promoters to go into that district.

Mr. A. J. LAWSON, Engineer and Manager to the promoters, said the present generating stations had a capacity of 70,000 8 c.p lamps. The proposed addition would give them a capacity for supplying 120,0 0 lamps. The demands on the Company were largely increasing in St Luke's, in Clerkenwell, in Holborn and St. Giles, and in Wandsworth. At the latter place, when the present site was enlarged, they would have a capacity to supply 240,000 8 c.p. lamps, and would possess 10,600 H.P. At Camberwell they would get under the Bill, with their existing works, about the same capacity as at Wandsworth. But in all cases 25 per cent. must be taken off for reserve. The demand at Wandsworth would be for 180,000 lamps in 5 years in Camberwell 100,000 lamps and in St. George the Martyr and St. Olave parishes (supplied from Camberwell) 30,000 lamps, making altogether 310,000. In all the areas the demand in five years was expected to reach 440,000 lamps. The proposed Camberwell station, on the Peckham branch of the Surrey Canal, was on a good site. They would get all the water required for condensing, and the site also afforded cheap carriage of coal. Both these conveniences formed important factors in the economical production of electricity. The Company did not at present want to connect their works north of the Thames with those on the south side. They did, however, desire to connect the works on the north side and those on the south side with each other. St. George's-in-the-East was asking for a supply of electric lighting, but the Company could not get there without the compulsory powers sought in the Bill. The petitions against the Bill resolved themselves into questions of compensation, or were based on a misconception. In the matter of charges the Company had offered an all-night supply for 3d. per unit, the ordinary charge being 7d. for the first hour and a-half and 3d. afterwards. As to account-keeping, at St. Luke's there were three separate systems of accounts, two of which applied to the one district of Holborn. They had to do that because the Company had obtained three Orders. The supply for the whole of that district came from one place, being produced by the same set of engines. In the case of Camberwell the circumstances were different, as the Company had a separate purchase clause in regard to that place. They had, therefore, excluded it from the accounts clause in the Bill. Their supply to Whitechapel would last five years they estimated; at the end of that time the works would have to be extended, and they would then have to extend the existing station. Whitechapel had obtained an Order for the supply of electricity, had asked for tenders, and had made a contract for carrying out electricity works. To get to St. George's-in-the-East it would be convenient to pass through both Whitechapel and Bethnal Green. There was room at the St. Luke's generating station for two more sets of engines. The works were sufficient for the district at present But even if they were not proposing to supply the outlying districts they would have to come to Parliament for power to extend their works. The Company were seeking to supply 12 new districts covering 28,000 acres, with a population of 1,213,000. He did not think the Company would require further generating stations for these districts. They would extend the existing stations. The Company's cables would not injure the water company's mains. The cables would carry an alternating current, and there would, therefore, be danger of electrolysis in the case of the water pipes.

Mr. WEDDERBURN, Q.C. (for the Blackheath and District Electric Light Co.), cross-examined witness to show that the promoters were not applying for power to supply any district which would require them to go through the district of the petitioners. Witness, however, said that it was desirable to have wayleaves to supply not only districts which they at present possessed, but which in the future they might acquire.

By Mr. ARNOLD STATHAM (for the parishes of Islington and Lambeth): The promoters were seeking to traverse the district of Islington in order to supply Hackney, as they were applying for an order for that district.

By Mr. TALBOT (for the Camberwell Vestry): The Camberwell Vestry had a purchase clause in the Company's original Provisional Order relating to that district.

Digitized by Google

Do you propose to give powers of purchase in regard to the proposed new generating station at Camberwell?

Mr. PEMBER, Q.C.: We do not propose to deal with that matter at all. We propose to leave it to the general law to say whether or not the original purchase clause will include the generating station for the construction of which powers are now sought.

Cross-examination continued: It was proposed to use the new generating station in Camberwell for the supply of the whole of their southern districts in case of emergency. It was not proposed to go east of Camberwell.

By Mr. DICKENSON (for the District Board of Wandsworth): The Wandsworth generating station would be used if necessary for the supply of outside districts. The local authority had the right to purchase, after a specified period, but only that part of the undertaking used for the supply of Wandsworth. When the proposed works were carried out it would be impossible to dissociate the part of the works supplying Wandsworth from the part supplying other places.

The Committee then adjourned.

HAMPSTEAD, EUSTON AND CHARING CROSS ELECTRIC LINE.

On Monday, a Select Committee of the House of Commons, presided over by Mr. Jeffreys, began the consideration of a group of Bills, having for their object the provision of electric railway facilities on the north side of the Thames. The first was the Central London Railway Bill, but the opposition had been withdrawn.

The Committee then considered the Hampstead, Euston and Charing Cross Railway.

Mr. WORSLEY TAYLOR, Q.C., for the promoters, said the scheme was authorised originally in the session of 1893, and was one of several similar proposals specially considered by a strong Joint Committee of Parliament, and generally approved in 1892. The object was the relief of the congestion of traffic in the centre of London, and the facilitation of traffic from that centre outwards to a boundary which, owing to the rapid and continuous growth of London, must always be a receding one. The promoters wished to obtain an extension of time for the taking of the necessary lands and the construction of works already sanctioned; to secure authorisation for the construction of three new railways which would greatly improve the scheme both in the interests of the public and of the Company; and as a natural consequence of the extended works, the raising of further capital. The present Bill would bring the proposed line in direct connection with the Midland at Kentish Town, the North-Western at Euston, and the South Eastern at Charing Cross. The Directors of all three lines approved the Bill. The length of the line was 4½ miles. Dealing with the petition of the County Council asking more favourable provisions as to workmen's trains, counsel said he thought the Company were already sufficiently burdened by the obligations imposed upon them by the Cheap Trains Act. The promoters were, however, desirous, if possible, of meeting the County Council in the matter, and he suggested the insertion of a similar clause to that put into the City and Brixton Bill last year providing that at least 12 trains should be run before 7 a.m. at a charge of not more than ½d. per mile, and that the holder should be entitled to return by any train during the day.

(Later in the day a clause was agreed to extending the time up to which cheap trains should be run to 8 a.m. at the termini, and fixing 1d. as the charge for the single and 2d. for the double journey, the holder to have the right to return by any train during the day.)

Mr. A. WILLIS, General Manager of the South Eastern Railway, gave evidence generally in support of the scheme. The new scheme, by which a connection would be made between the South Eastern at Charing Cross, and the electric line, by means of lifts or a subway at Craven-street or Villiers-street, would be of great assistance to the local traffic; and he considered that it was the best electrical enterprise that had yet been promoted in London.

Mr. W. R. GALBRAITH, C.E., Consulting Engineer to the London and South-Western Railway, and Engineer to the Waterloo and City Railway, said he was, in conjunction with Sir Douglas Fox, engineer of the present scheme. The levels at Charing Cross had been altered from those set down in the original scheme to avoid underpining. The cost of the proposed new lines and works was estimated at £290,000.

Mr. GEO. H. TURNER, General Manager of the Midland Railway, strongly supported the scheme. He thought any scheme which dealt with the difficulty at present confronting the managers of all the great lines—viz., that of dealing with suburban traffic—should be encouraged.

The Bill was reported to the House for second reading.

LEGAL INTELLIGENCE.

W. T. Glover and Co. (Limited) v. William James Glover and Co. (established 1818) (Limited).

On Monday, in the Chancery of Lancashire, before Vice-Chancellor Hall, Q.C., leave was granted to serve notice of motion for Monday next in this action, which is brought by the plaintiffs for an injunction to restrain the defendants from carrying on business as makers of electric cables, wires, &c., under any title of which "Glover" forms a part.

Factory Prosecution.

At Bilston County Court, Mr. N. C. A. Neville, stipendiary magistrate, gave judgment in the prosecution of the Bilston District Council, for not posting up a copy of the Factory Act in the market hall, which is lighted by electricity produced on the premises. At the first hearing it transpired that the building was used for the generation of electric current for the market hall. The contention of the prosecution was that the hall was a factory because electricity was manufactured by way of trade for the purpose of gain. The defence was that the building was not used for the purpose stated, and that it could not be a factory, because electricity was not an article as defined by the Act. In giving judgment Mr. Neville said that according to the dictionary an article was described as a commodity, and a commodity was that which was useful or advantageous. Electricity, being made at the works, required mechanical power and manual labour, and it would, therefore, come within the meaning of the Factory and Workshops Act if it was an article—as he believed it was—and was used for the purpose of gain. Electricity could be manufactured, stored, moved about, converted into different uses, and stolen. The Council obtained a benefit by producing current in the market, and it must be said to be a gain within the meaning of the Act. A nominal penalty of 2s. 6d. and costs (£1. 17s. 6d.) was imposed.

Alexander v. Margowski and The Automatic Telephone Co. (Limited).

In the Chancery Division yesterday (Thursday), before Mr. Justice North, Mr. M. Alexander sought to obtain an interim injunction restraining Mr. Max Margowski and the Automatic Telephone Co. from acting upon a resolution for removing the plaintiff from his office as director. The resolution was said to have been passed at an extraordinary general meeting of the company, but the plaintiff alleged that no such resolution was ever put to the meeting, which was of a very disorderly character throughout, and that had it been put to the meeting, it would have been lost by an overwhelming majority. In giving judgment, his Lordship said he could not see a tittle of evidence to justify the statement of the Chairman (Mr. Margowski) that the resolution had been carried by a tremendous majority. The proceedings at the meeting were irregular from beginning to end, and it was a disgraceful act on the part of the Chairman to declare that the resolution had been carried when it was not put to the meeting at all. The Chairman knew very well that the resolution had not been carried, and if there had been a show of hands upon the subject, it would have been enormously in favour of rejecting the resolution. The Chairman and a number of persons present at the meeting seemed to have forgotten altogether how to behave as gentlemen and men of business. The attempt to remove Mr. Alexander from his office as director failed, and the injunction would be granted; but as the parties all round were wrong from beginning to end, he would not give either side a penny of costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NOW READY.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s. *New edition ready May 1, 1899.*

"The Electrician" Electrical Trades' Directory and Handbook for 1899.—The "Big Blue Book" for 1899 is Now Ready. The Directory Division has been corrected up to Feb. 8, 1899, and all the latest new names, changes of address, &c., will be found included. The Handbook Division has been much extended, many valuable tables having been added. The volume contains, also, the large Sheet Tables of Electricity Supply Stations and Electric Railways and Tramways, finally corrected to Feb. 9, 1899. The price of the Directory and Handbook remains the same—10s., post free 10s. 9d.; abroad, post free, 12s. (United States 13s. 6d.).

TENDERS INVITED.

The *Poplar* (London) District Board of Works invite tenders for the execution of the following contracts:—(*a*) Engine and pump room equipment and all electrical plant except battery; (*b*) boiler house equipment; (*c*) battery and battery stands; (*d*) public street lighting. Specifications, &c., may be obtained from the clerk to the Board (Mr. Leonard Potts), 117, High-street, Poplar, London, E., on and after 23rd inst. Further particulars are given in an advertisement, and tenders must be sent to Mr. Potts by 10 a.m. of Tuesday, April 25.

The *Tynemouth* Corporation invite tenders for the supply and erection of the following plant:—(2) boilers, &c., (3) economisers and fittings, (4) ejector-condenser, circulating pumps, tanks and pipework, and water cooler, (5) pumps, feed pipes, &c., (6) travelling crane, (7) traction switchboard, (8) lighting switchboard, (9) accumulators, (10) cables, and (11) traction steam dynamo. An advertisement contains additional information. Specifications, &c., may be obtained on and after 20th inst., at the offices of the consulting engineers (Messrs. Lacey, Clirehugh and Sillar), 2, Queen Anne's Gate, Westminster, S.W., and tenders must be sent in to the town clerk (Mr. Horatio A. Adamson), by noon of April 15.

The Great Northern Railway Co. (Ireland) invite tenders for the following works in connection with their line between Sutton and Howth:—Cables for feeders, returns, potential lines, &c., 6 motor and 6 trailer cars, overhead construction, and battery and booster. Specifications can be obtained from the secretary (Mr. T. Morrison), Amiens-street, Dublin, with whom tenders must be lodged by April 20. Specifications may also be seen at, but not obtained from, the office of Prof. Alex. B. W. Kennedy, 17, Victoria-street, London, S.W. Further particulars are given in an advertisement.

As advertised elsewhere the Directors of the Lancashire and Yorkshire Railway invite tenders for the supply of stores during the 12 months ending April 30, 1900, including signal and telegraph fittings, signal, telegraph and electric light wires, screws, oil, springs, wire, &c. Further particulars and forms of tender may be obtained at the Stores Department, Osborne-street, Manchester, and samples may be inspected at the Sample Room from the 20th to the 30th inst. inclusive. Tenders must be lodged with the secretary (Mr. C. W. Bayley), Hunt's Bank, Manchester, by 10 a.m. of Monday, April 3.

The Corporation of *West Hartlepool* invite offers from firms or companies for "free" wiring of premises in the district. Further particulars are given in an advertisement, and offers must be lodged with the town clerk (Mr. Higson Simpson) by April 15.

The Electric Light committee of the *Salford* Corporation invite tenders for stores, particulars of which are set out in an advertisement. Tender forms, &c., may be obtained from the borough electrical engineer (Mr. Chas. L. Turner), Walness-road electricity works, Broughton, Salford.

As announced in an advertisement, the *Rhyl* District Council invite terms from engineers for preparing plans, specifications, &c., for a refuse destructor. Further information may be obtained from the town surveyor (Mr. Robert Hughes). Terms must be in by April 3.

The *Edinburgh* Corporation invite tenders for installing the electric light at the City Chambers (extension buildings). Specifications, &c., can be obtained from the resident electrical engineer (Mr. F. A. Newington), 5, Dewar-place, and tenders must reach the town clerk (Mr. Thomas Hunter, W.S.), City Chambers, Edinburgh, by 10th April. See also advertisement.

The *Barking* District Council invite tenders for the supply and erection of one 80-kilowatt steam dynamo, with necessary pipework and accessories. Tenders, addressed to chairman of Council, by 27th inst.

The *Sunderland* Corporation invite tenders for (*a*) india-rubber covered cables, (*b*) cast and wrought iron pipes and street service boxes, (*c*) stoneware casings and bearers, and (*d*) house fuse boxes. Tenders, addressed to Chairman of Lighting committee, must be delivered at town clerk's office by 30th inst.

The *Doncaster* Corporation invite tenders for the supply and erection of (*b*) three mild steel Lancashire double-flued boilers; (*c*) three sets of steam dynamos, two sets of larger steam dynamos, condensing plant, &c., and a 6-ton overhead traveller; (*d*) storage battery of 136 cells, having a capacity of 750 ampere-hours; (*e*) electrical instruments and other apparatus; (*f*) underground armoured cables, &c. Tenders to town clerk by 28th inst.

The Corporation of *Peterborough* invite tenders for the supply and erection of the following electric lighting plant:—(1) Lancashire boilers and economiser; (2) Steam dynamos, balancers and boosters; (3) Secondary battery and accessories; (4) Switchboard and instruments; (5) piping, tank, condensers and pumps; (6) insulated cables. Tenders to town clerk by Thursday, April 20.

The *Paddington* (London) Guardians invite tenders for wiring the workhouse in Harrow-road. Tenders before 5 p.m. of 28th inst.

The Electric Lighting committee of the *Rothesay* Town Council invite tenders for the supply and erection of two 20 H P. coupled engines and dynamos, switchboard, cables, arc lamps and posts, feed pump, &c. Tenders to town clerk by noon of 27th inst.

The *Southend* Corporation invite tenders for the temporary transfer of their provisional order. Tenders to town clerk by April 6.

The *Wolverhampton* Lighting Committee invite tenders for supplying and erecting about 110 tons of steel stanchions, girders and decking at electricity works. Tenders to borough engineer by April 8.

The *Morecambe* District Council require tenders for mechanical stokers for two Babcock-Wilcox boilers. Particulars from Engineer.

The *Coventry* Corporation invite tenders for extension of the electricity buildings. Tenders to town clerk by 28th inst.

The Guardians of the Poor of *Rochdale* Union require tenders for a complete electric light installation at the workhouse buildings and cottage homes. Specifications, &c., can be obtained from the consulting engineers (Messrs. Crews and Handford, Cross-street Chambers, Manchester), and tenders must be sent in to Mr. R. A. Leach, clerk, Union Offices, Townhead, Rochdale, not later than April 12. An advertisement gives further particulars.

The *Edinburgh* Corporation invite tenders for the supply and erection of water tube boilers at Dewar-place station. Tenders to town clerk by April 3.

The *Aberdeen* Corporation invite tenders for the supply and erection of the following materials for the equipment of their George-street and Woodside tramway route:—(*a*) permanent way and roadwork, (*b*) overhead line construction, (*c*) feeder and test cables, (*d*) tramway cars and all accessories, and (*e*) switchboard, instruments, &c. Tenders to town clerk (Mr. W. Gordon) by 10 a.m. of 29th inst.

The *Aberdeen* Corporation also invite tenders for supply of:—(1) two Babcock-Wilcox boilers, (2) one 180-kilowatt steam dynamo (Belliss or Willans and Robinson engine), with steam and exhaust pipes, and one 75-kilowatt balancing set. Tenders to town clerk by April 5.

TENDERS RECEIVED AND ACCEPTED.

The Greenock Board of Police have accepted the following tenders:—Babcock and Wilcox (water tube boiler, economiser and mechanical stokers), £1,956; Carrick and Ritchie (overhead travelling crane), £450; India Rubber Company (steam dynamos, boosters, switchboard, accumulators, complete piping arrangements, feed heater, and feed pumps), £11,517. 10s.; Callender's Company (low tension mains, and erection of arc lamps, poles, &c.), £12,603. 3s. 2d. The tender of Mr. M'Ewan has been accepted for the erection of the electricity building.

The following tenders have been received for the electric lighting of Emmanuel Church, South Croydon:—

Brush Company (*accepted*)	£230 0	Moody Bros.	£263 12
Planet Elec. Eng. Co	385 0	Bergtheil and Young	255 0
Belshaw and Co.	303 0		

The contract is to be carried out under the supervision of the consulting engineer, Mr. W. Howard Tasker, M.I.E.E.

The Fire Brigade committee of the London County Council have accepted the offer of the National Free Wiring Co. to extend the wiring at the chief fire station, Southwark, S.E., for £86. 10s.

The Wolverhampton Corporation have accepted the tender of Mr. H. Gough for extending the electricity station building.

The West Hartlepool Corporation have accepted the tender of Mr. George Marshall, Darlington, for the erection of electricity supply buildings at £11,473, to be completed within eight months.

The Fulham Vestry have given the contract for the erection of electricity supply and refuse destructor buildings to Mr. G. Minter, at £22,970. Messrs. Wilkinson Bros., whose tender was originally accepted, declined to accept the Vestry's condition that the works should be completed in six months. Mr. Minter guarantees to erect the buildings in 10 months.

The tender of Messrs. Gimson and Co. for the supply of cast-iron tank at the Wimbledon electricity works at £109. 10s. has been accepted.

APPOINTMENTS VACANT AND FILLED.

The Middleton Corporation invite applications for the position of resident electrical engineer. Further particulars are given in an advertisement, and applications (addressed to chairman of the Gas and Electric Lighting committee) must be delivered at the office of the town clerk (Mr. Frederick Entwistle) by 29th inst.

A thoroughly competent manager is required for large india rubber works to be established on the continent. Some further particulars are given in an advertisement.

As advertised elsewhere, the Edinburgh Corporation invite applications for the position of assistant to the superintendent of mains. Applications to resident electrical engineer (Mr. F. A. Newington), 5, Dewar-place, Edinburgh, on or before Monday, April 3.

Digitized by Google

The Wolverhampton Corporation require a mains superintendent, at a commencing salary of £104 per annum. Applications to borough electrical engineer (Mr. C. E. C. Shawfield) by Tuesday, April 4. See advertisement.

There are vacancies for two improvers as switchboard attendants at the Portsmouth electricity works. Applications by April 3. See advertisement.

The Corporation of Devonport require an electrical engineer competent to devise electric lighting and tramway scheme for the borough. Applications to town clerk by 29th inst.

The Stafford Gas and Electricity committee require a chief clerk and cashier. Salary £130 per annum. Applications to Town Clerk by noon 25th inst.

Mr. Herbert A. Jones has been appointed manager of the Phœnix Dynamo Manufacturing Co. Mr. Jones has been with the E P.S. Co. for about nine years, formerly upon their laboratory staff and for the last six years as commercial representative in the north of England and Scotland.

Mr. Angus M'Lean, B.Sc., lecturer and demonstrator in experimental physics at Glasgow and West of Scotland Technical College, has been appointed principal of the new Paisley Technical School at a salary of £300 per annum. Mr. M'Lean was educated at the Glasgow University where he graduated B.Sc. with honours in mathematics and natural philosophy.

Mr. William Deeley has been appointed clerk of works in connection with the erection of the Buxton electricity station building.

Mr. M. Roberts, superintendent of the Post Office general factory at Mount Pleasant, London, has been appointed by the Postmaster-General second assistant engineer-in-chief to the Post Office.

BUSINESS NOTICES.

In consequence of increase of business, Messrs. Williamson and Joseph (Limited) have appointed Mr. John G. Dixon, 55, Norfolk-chambers, Norfolk-street, Sheffield, to represent them in the north of England from Derby. Messrs. Ross and Co., 95, Bath-street, Glasgow, have been appointed agents for Scotland, and Mr. A. F. Sargeant, 51, Lincoln's Inn, Corporation-street, Birmingham, will represent the company in Birmingham and surrounding districts.

The offices of the South London Electric Supply Corporation (Limited) will, from March 25 next, be removed from 28, Victoria-street, Westminster, S.W., to Bengeworth-road, Loughborough Junction, London, S.E.

Owing to increase of business in the Leeds district Messrs. Laing, Wharton and Down (Limited) have appointed Mr. Douglas J. Callow (until recently engineer to the Brewster Engineering and the Reedy Elevator Cos. of New York) as district manager and representative. Mr. Callow has had experience in contracting work in this country and in America, and it specially conversant with electric light, power and lift work. The telegraphic address is "Laying," Leeds; telephone, 2,247 Central. Mr. C. T. Taylor remains on the staff as assistant engineer.

The editorial and general offices of *Lightning* have been removed to 8, Bream's-buildings, Chancery-lane, London, E.C.

The following correspondence has appeared in connection with the recent issue of the prospectus of William James Glover and Co. (established 1818) (Limited):—

"With reference to the advertisements which have appeared of a new company under the name of William James Glover and Co. (established 1818) (Limited), described as electrical cable makers, wire drawers, &c., I desire to call the attention of the public to the fact that this company has no connection with our company, W. T. Glover and Co. (Limited) or the business carried on by our predecessors, W. T. Glover and Co., the well-known manufacturers of electric cables, of this address. My directors have insutructed our company's solicitors to take proceedings against the new company to prevent the use of the name of 'Glover' in connection with electric cables, and a writ has been issued for this purpose and will be served and further proceedings taken without delay.—For W. T. Glover and Co. (Limited), S. HARTFORD, Secretary, Salford, Manchester, March 18, 1899."

"Our attention has been drawn to a prospectus issued by Messrs. William James Glover (established 1818) (Limited), in which it is stated that the company had taken over, from a Mr. G. E. Heyl-Dia, an English patent, No. 2610, of 1899. In order to avoid any possible misunderstanding, we beg to draw attention to the fact that it is a mistake to describe this as a patent. It is at present merely an application for the grant of a patent, and for an idea that we regard (from the description given in the prospectus) as a serious infringement of one or more of this company's existing patents; and further, it is our intention in due course to strongly oppose the grant of the patent on this ground. We may mention that we are filing a caveat at the Patent Office in connection with this matter, and intend to neglect no proper steps to protect our interest.—For the British Insulated Wire Company (Limited), EDWD. TRACEY, Secretary, March 18, 1899."

"We have read Messrs. W. T. Glover and Co's. (Limited) letter, and we beg to say our firm has been in existence since the year 1818, under the same name, William James Glover and Co. Cable making is not a monopoly of Messrs. W. T. Glover and Co. (Limited), of Salford, or any other company. Before registering our company, we not only consulted our solicitors as to the name of this company, but have also submitted the matter to the decision of the Registrar of Joint Stock Companies, at Somerset House, and obtained his approval and certificate of incorporation. The animus prompting this letter to the papers is obvious, and we regret that Messrs. W. T. Glover and Co. (Limited), of Salford, fear the competition of this company so much as to lead them to take such a step.—WILLIAM JAMES GLOVER AND CO. (established 1818) (LIMITED), G. E. HEYL-DIA, Managing Director, 55, Market-street, Manchester, March 20, 1899."

"In reply to the letter of the British Insulated Wire Co., we beg to say that the patent Heyl-Dia, 1899, does not form any part of the assets included in the valuation of this company, nor is the company in any way dependent upon this patent for the making of electric cables. The complete specification in connection with Mr. Heyl-Dia's application has been filed, and in due course the British Insulated Wire Co. will be able to obtain a copy thereof, but until then we fail to see that there is any justification whatever for their letter. This company, we may say, is indemnified by Mr. Heyl-Dia against any costs that may be incurred in perfecting the patent in question, and the patentee in due course will be prepared to meet the opposition of the British Insulated Wire Co. or any other objectors and maintain his title to the invention. The object and intention of the British Insulated Wire Co. is obvious, but unworthy of them.—WILLIAM JAMES GLOVER AND CO. (established 1818) (LIMITED), G. E. HEYL-DIA, Managing Director, 55, Market-street, Manchester, March 20, 1899."

BANKRUPTCIES, LIQUIDATIONS, &c.

A meeting of the Edison-Gower-Bell Telephone Co., of Europe, Limited (old company), will be held on April 27 at 186, Shaftesbury-avenue, London, W.C., to receive an account of the winding-up. Mr. R. Rodgers is liquidator.

Claims against Veale and Co., Limited (old company), St. Austell, must be sent in by April 12 to the liquidator, Mr. J. M. Coon, St. Austell.

A meeting of Pearson's Automatic Fire Indicator Co. (Limited) will take place at 100, St. Martin's-lane, London, W.C., on April 21, to receive an account of the winding up. The undertaking has been acquired by the Pearson Fire Alarm System (Limited).

A receiving order has been made against A. W. Charles and J. S. Blackwell, trading as the Central Electrical and Engineering Co., Church-gate, Leicester, and 22, Kennington-road, London, S.E, on their own petition. The first meeting of creditors takes place on 28th inst., and the public examination on April 26, both at Bankruptcy-buildings, London, W.C.

The summary of the affairs of Frederick Marson, electrician, &c., 1, Poplar-avenue, Leicester, shows unsecured liabilities, £478. 5s. 8d., assets estimated at £675. 7s. 1d., surplus £197. The debtor attributes his failure to ill-health. He started in business as an ironmonger in 1886, and has traded at various addresses at Leicester since that date. He executed a deed of arrangement in May last, and undertook to pay 20s. in the £ in four quarterly instalments, but nothing has been paid under this arrangement.

Plant for Sale.—Messrs. Laing, Wharton and Down, 82A, New Bond-street, W., have electric lighting plant for sale, further particulars of which are given in an advertisement elsewhere.

The Electrical Company have for disposal a complete electric lighting plant. Further particulars are given in an advertisement, and the whole may be seen in working order at 122, Charing Cross-road, London, W.C.

Electrical Plant Contracts.—The following contracts for electric lighting and traction plant have been recently placed with the British Thomson-Houston Co.:—

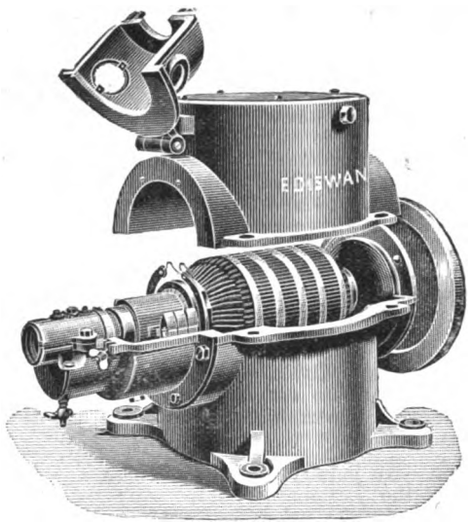
Extensions to overhead line construction, for Leeds city tramways; two direct-connected 1,100 H.P. lighting sets (Belliss engines), for Glasgow Corporation; two 93-kilowatt generators and Belliss engines, three-machine booster and two-machine booster, for Govan; two 500-kilowatt extension generators, for Sheffield tramways; a 500-kilowatt, 2,100-volt, direct-connected alternator and Belliss engine, for Croydon; two 325-kilowatt, direct-connected generators and Belliss engines, with switchboard, for Messrs. Vickers, Sons and Maxim (Limited), Sheffield; nine double-motor equipments, for Dudley and Stourbridge electric tramways; one 150-kilowatt and one 75-kilowatt generators and four-machine booster balancer, for Lowestoft Corporation; three car trucks, with double-motor equipments and magnetic brakes, for Manchester Corporation tramways; six double-motor equipments, with magnetic brakes, for extension to Colombo tramway plant; two 220-kilowatt generators, direct-connected to Ball and Wood engines, for proposed Wolstanton power station of Potteries extension tramways.

Retirement.—Mr. John Doherty, superintending engineer of the north-western district of Post Office telegraphs, retires on April 7, having reached the compulsory age limit of 65. Mr. Doherty has been associated with telegraph work since 1852 when, under the late Mr. W. T. Henley, he was engaged in superintending the laying of the underground telegraph of the Lancashire and Yorkshire Railway system between Manchester and Liverpool. The syndicate with which Mr. Henley was at that time connected afterwards became the Magnetic Telegraph Co., later (in 1851) the British Telegraph Co., and, still later, the British and Irish Tele-

Digitized by Google

graph Co. Mr. Doherty, in 1858, was connected with the construction of the telegraph lines of the Red Sea Telegraph Co. He subsequently returned to England and rejoined Mr. Henley at the North Woolwich Works and, in 1860, accepted service with the United Kingdom Telegraph Co., whose executive officer in the Manchester district Mr. Doherty remained until the period of the acquisition of the telegraphs by the State in 1870. Since that time he has held the position from which he now retires.

Ediswan Enclosed Motor (New Type).—We illustrate below the new type of Ediswan enclosed motor, recently introduced. The body of this motor consists of two steel castings, which form the enclosing framework and the magnetic circuit. They are fitted together at a broad joint, which in no way interferes with the completeness of the magnetic circuit. The material used is a specially soft cast steel having a magnetic permeability superior to wrought iron, enabling the weight of the motor to be reduced to the smallest amount possible. Gun-metal bearings are fitted in cast-iron brackets, which form the end pieces of the motor. The brasses are several times as long as the diameter of the shaft. Great stiffness is thus secured, and accessibility to the wearing parts is perfect. Effective lubrication is provided for by large oil chambers cast in the lower parts of the brackets, capable of holding an ample supply of oil for a considerable time. Two chains are provided to each bearing, and the oil most effectively distributed over the rubbing surfaces by means of channels, and carried back into the reservoir. The parts are arranged so that it is impossible to overfill the reservoirs, and thus cause the oil to creep into the main body of the motor. The smallest sizes of these motors have two brushes each side,



the larger ones two or more according to the output. All the brush gear terminals and internal connections are at once accessible by lifting the lid provided over the commutator box. The upper half of the body can be easily removed with its own magnet coil attached. The connecting wires to the source of supply are passed in through ebonite glands in the commutator box, placed opposite to the terminals into which those wires have to go. The armature is of the slotted drum type, and the whole motor is of substantial design, capable (it is claimed by the makers) of running continuously without over heating at the full load marked. It is designed also to stand 20 per cent. over-load for an hour or more without injury. It is completely enclosed and dust proof, the commutator cover having a glass window in it, enabling the commutator to be inspected without opening the case.

Volenite.—Some time back, damaging statements were published concerning the works and process owned by Volenite, Limited, and Mr. H. J. Fuller, M.Inst.C.E.I., was appointed to inspect the Company's works at Alperton, Wembley, and to report generally. His report is just published, and is very favourable to the Company's prospects. On the subject of the value of volenite as an insulating material, Mr. Fuller reports: "I am only specially interested in two uses of the material, that for making joints and that for electrical purposes. I have had a piece of the original and greatly inferior stuff put into a previously troublesome joint in the principal steam main of, probably, the largest boiler works in England. It has remained perfectly tight and satisfactory for more than ten months, and is as good to-day as when first put in. As regards di-electric qualities, I have submitted to the largest electrical firm in the world certain samples. I have received the definite result of the tests (applied not with the object of finding out how good the stuff might be, but to find out its weak points, if any), and I am in a position to state that a piece of only seven one-hundreths ($\frac{7}{100}$ths) of an inch in thickness was only pierced by a current at an electrical pressure of 27,000 volts; while another piece, $\frac{13}{32}$nds of an inch thick, resisted the application of 59,000 volts. These pressures are respectively 54 and 118 times the pressure to-day employed in electric traction. In long-distance transmission the cost of the transmission line decreases as the pressure of current increases in a well-understood ratio, high electrical pressure demands absolutely safe insulation, and the absence of the latter has been a drawback hitherto seriously felt. I have suggested to your chemist the preparation of an insulating varnish for application to armature windings, &c., which would be of the highest value, and I understand that he is able to manufacture this. My opinion is that operations with your new fibre have either already resulted in, or are on the verge of reaching, nothing more nor less than chemically manufactured india-rubber at a nominal fraction of its cost. You should be able to command a very large business for electrical purposes."

Alleged Infringement.—In connection with a note appearing in our last issue we have received the following:—

TO THE EDITOR OF THE ELECTRICIAN.

Sir: With reference to the paragraph under the above heading, in your issue of the 17th inst., will you permit me, as author of the Defendant's book referred to, to point out that it was largely an amplification of articles published by me in January and February, 1894, and of a book published by me in March, 1896. Two of the expressions chiefly relied upon by the Plaintiff as evidence of plagiarism were actually used by me in an article published in the *Practical Engineer* in May and June, 1896. As Mr. Lewis's book was only published late in 1896, and was never seen by me before February, 1897, the weakness of the plaintiff's case is apparent. Unfortunately our counsel was not called upon for any reply, and had, therefore, no opportunity of exposing the frivolity of the charges made. Had you been acquainted with the facts of the case, or had you even heard the plaintiff's speech, you would hardly have made the comments you have or expressed such sympathy with him. As I am sure you desire to be just to both your readers and myself, I trust you may find space for this letter.—Yours, &c., FRANCIS G. BURTON.

Poynton, Cheshire, March 20, 1899.

We commented upon the case as it was reported, and our sympathy is certainly with Mr. Lewis in this matter, mainly from the fact that in the remarks made by Mr. Justice Cozens Hardy he distinctly stated "that use had admittedly been made of the plaintiff's book." If this is so, justice demands that due acknowledgment of this indebtedness should have been made by the defendants in their book. We have a letter before us from Mr. Lewis which states: "My words had been used by the defendants in no less than 109 paragraphs on the same subject, and a number of my forms copied almost *verbatim*." If this statement is accurate, or fairly accurate, Mr. Lewis is suffering from a great wrong. We think the tone of Mr. Burton's letter above hardly improves matters. We have certainly no desire to misjudge the particular matter under notice. Our comments were directed against an extremely prevalent custom of culling wholesalely from published works in order to produce cheap editions of books which may reasonably be expected to have a fair sale. Our remarks apply particularly to pocketbook and reference book compilers, who are by far the greatest sinners in this regard.

Langdon-Davies Motors.—The Langdon-Davies Electric Motor Co. have issued the terms upon which the hire and hire-purchase of motors can be arranged, the object of the Company being to supply these motors to small users who cannot afford to buy them outright.

Castings.—Messrs. John Shaw and Co., Maryhill Iron Works, Glasgow, forward a copy of a new list of castings, which include dynamo beds, armature castings, cast-iron columns, pipes and a large variety of jobbing castings of all kinds.

"The Journal."—Parts 137 and 138 of the *Journal* of the Institution of Electrical Engineers are now ready. Particulars of the contents of these numbers are sent out in an advertisement.

Directory of Delagoa.—A useful directory and year-book of local information regarding the town and port of Lourenço Marques has been sent us by Messrs. A. W. Bailey and Co., of that town. The information includes much that is likely to interest traders on this side. It is well got up, and is published at 2s. 6d.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from March 15 to March 21, with the ports of destination:—

Argentina—Buenos Ayres, £3,973 (including £539 telegraph material); La Plata, £108 (including £88 telegraph material). *Australasia*—Brisbane, £227 (including £209 telegraph material); Melbourne, £47; Sydney, £554; Wellington, £369 (including £190 telegraph material). *Belgium*—Ghent, £25; Ostend, £85. *British Guiana*—Berbice, £13. *Burma*—Rangoon, £16. *Ceylon*—Colombo, £65. *Chili*—Boca, £106 (telegraph material). *China*—Shanghai, £229; Tientsin, £104 (telegraph material). *Ecuador*—Limon, £86 (telegraph material). *Egypt*—Alexandria, £173. *France*—Boulogne, £159. *Germany*—Hamburg, £200. *Holland*—Amsterdam, £200. *India*—Bombay, £316 (including £180 telegraph material);

Digitized by Google

Calcutta, £258. *Mexico*—Santa Cruz, £35. *Norway*—Christiania, £63. *Russia*—Odessa, £20 (telegraph material). *South Africa*—Cape Town, £328; Delagoa Bay, £95; Durban, £446 (including £103 telegraph material); Port Elizabeth, £391. *Spain*—Barcelona, £31. *Straits Settlements*—Singapore, £120. *Sweden*—Gothenburg, £72; Stockholm, £128 (telegraph material). Total £9,042, against £83,403 in the corresponding week last year (March 16 to March 22).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Alleged Fraud.—At the Guildhall Police Court yesterday (Thursday) Claud Vautin, electro-metallurgist, &c., was again charged with obtaining securities and bonds by fraud. The case was again adjourned.

Ayr.—On the recommendation of the burgh electrical engineer (Mr. Arthur J. Fuller), the Corporation have decided to fix the charge for current for motive power at 3d. per unit, with a minimum charge of 15s. per annum.

Bangor-Donaghadee Electric Tramway.—An inquiry into the engineering details of this tramway has been held at Bangor. All the local authorities affected by the scheme had signified their approval. Mr. Plummer, C.E., engineer to the promoters, submitted plans, and said the overhead trolley system would be adopted. The gauge would be 3ft. 6in., and 70lb. rails would be put down. There would be eight bogie cars, lighted and heated electrically. The generating station would be near Groomspout. After some objection to minor details of the scheme had been heard the inquiry closed.

Blackburn.—The mayor has been invited to open the electric tramways on the 29th inst. The cars on the Preston-road section commenced running on Monday.

Bridge of Allan (N.B.).—The Lighting committee is considering a proposal by Edmondson's Electricity Corporation for electrically lighting this village, together with Dunblane.

Cable Communication with Australia.—Owing to the simultaneous interruption of the Government landlines in South and West Australia, it has been, this week, impossible to transmit telegrams beyond the Eastern Extension Company's cable terminus at Port Darwin. Communication was restored yesterday.

Chester.—Extensions of the electric lighting mains, estimated to cost £1,500, were authorised at the last meeting of the Council, when it was also decided to adopt electric lighting in a number of streets in which mains are already laid, at a cost of £530.

Church Lighting.—SS. Peter and Paul's, Cork, is one of the latest churches to adopt electric lighting. The wiring contract was executed by the local branch of Messrs. Dobsons and Curtis Bros. (Limited). The introduction of the electric light should add to the attractions of this handsome edifice, which is built on the decorated Gothic style, and is one of the finest churches in a city abounding in places of public worship. At all events there will be no further complaints of the deterioration of the internal decoration by gas. Current is taken from the mains of the Cork Electric Tramways and Lighting Co.

City of London.—The Common Council yesterday (Thursday) rejected Mr. Brooke Hitching's motion to approach the City of London Electric Lighting Company with a view to ascertain the price and terms on which the company would be prepared to sell their undertaking to the Corporation. In view of the forthcoming Board of Trade inquiry, it was considered that a discussion on the matter was inopportune.

Colwyn Bay.—The Council have adopted a report from their consulting engineer (Mr. S. V. Clirehugh), recommending the adoption of an extended scheme of electric lighting and the substitution of steam for gas driven plant. A further loan of £4,000 is to be raised.

Dublin.—The proposal of the Municipal Industries Syndicate, to take over the electricity undertaking of the Corporation, has been "taken as read."

Edinburgh.—From Feb. 23 to March 19 the applications for electric current were equal to 5,471 8 c.p. lamps, and the number connected up from the 1st to the 17th inst. were equivalent to 6,500 8 c.p. lamps. The Electric committee recommended the acceptance of an estimate amounting to £8,827 for the formation of a subway between the Macdonald-road station and Picardy-place.

Electricity in Rhodesia.—In the Telukive district of Rhodesia there is installed at the Bonsor Mine a 150 H.P. three-phase plant working at 600 volts. The current generated is used for lighting, hauling, pumping, corn cutting, and driving a sawmill. The Kaffir huts in the neighbourhood (occupied by whites) are lighted by electricity! All the plant is American.

Farnborough.—The Council have finally decided to transfer their electric lighting powers to Power and Traction (Limited).

Glasgow.—At a special meeting of the Corporation the report by Mr. H. F. Parshall on the generation of current for the tramways department was considered and approved. An abstract of the report appeared in our issue of the 10th inst.

Bailie Maclay announced that the Electricity Committee had already lighted up one-half of the electric car route between Mitchell-street and Springburn. The whole of the new engines and dynamos would be in working order within the next few days. The Committee was now in a position to supply all demands for current.

Grays (Essex).—In a supplemental report Mr. A. H. Preece estimates the cost of erecting a refuse destructor in connection with the proposed electricity station at £2,500. It has been decided to combine both schemes, and a committee has been appointed to visit places where destructors are in operation, and to collect information for the guidance of the Council.

Greenock.—The following amended offer has been made by the Directors of the British Electric Traction Co. in connection with the electric tramway scheme for this district:—Rental of Corporation line between Rue End-street and Berryburn, £1,050 a year; minimum quantity of electric current to be purchased each year by company from Corporation, 500,000 units, at 1¾d. per unit for first 200,000, 1½d. for next 100,000, 1¼d. for next 100,000, 1d. for next 100,000 and all power beyond. The company undertakes not to erect a generating station so long as the Corporation gives a satisfactory supply of power.

Islington (London).—The Works committee are to report upon an offer of the National Telephone Company to establish a large exchange, capable of accommodating 4,000 subscribers for Islington, provided the Vestry would give facilities for carrying out the work by means of underground wires.

Some time ago the Vestry let the contract for extending the electricity station building to Messrs. Patman and Fotheringham. This firm refused to sign the Vestry's declaration as to the payment of trade union rates of wages, though they offered to pay the full rate of wages in each class of labour as agreed upon between the Master Builders' Association and the trade unions. The firm had also intimated their objection to the condition that contractors should cause a list of the rates of wages paid to workmen to be exhibited in such a place on or contiguous to the work as should enable any workman engaged thereon to have free excess to the list. Other firms who submitted tenders had also intimated that they would not accept a contract if the Vestry's conditions were insisted upon. The Vestry decided that the conditions be waived on the present occasion.

Japanese Submarine Cable.—A submarine telegraph cable has been laid by the Japanese authorities between various points on the Japanese coast. The cable starts at Kuzuha and traverses the coast to Yamaguchi.

Leamington.—An inquiry was held here on Tuesday into the applications of the Leamington Corporation and the Midland Electric Lighting Co. for provisional orders. Mr. C. A. Russell, Q.C., for the Corporation, sketched the history of the Corporation's relations with the company, which commenced supplying current in 1887. He submitted that the last thing the company really wanted was a provisional order. They had begun the supply of current under an agreement with the Corporation, and they would not have applied for an order if they had not been driven to it. He contended that what the company wanted was perpetual and unlimited rights and privileges, and not an order. He asked the Board to grant the Corporation's application. Evidence was given, on behalf of the Corporation, to the effect that the supply of current was not satisfactory. Mr. R. Hammond, consulting engineer to the Corporation, said that it would be putting on the Corporation too onerous a burden in paying for the existing plant, &c., the price which was shown by the present capital of the company. He considered the clause proposed by the Corporation, to take over practically that portion of the plant which would be serviceable to them, was an extremely equitable clause, and one which should be satisfactory. It would be an injustice to ask the Corporation to take it over at cost price. He thought that with modern plant they would be able to supply electricity in Leamington cheaper than the company were now supplying it. Mr. Mahmorran, Q.C., for the Company, said his clients engaged in electric light supply in 1887, when electric lighting was in its infancy. It was not until 1897 that they were able to pay a small dividend and they felt that just at the time when there was some likelihood of getting a return for the expenditure incurred, it was more than hard—it was unjust—to seek to deprive them of their undertaking at a ruinous price, that is, if the suggested Board of Trade clause were inserted. He maintained that the present case required exceptional treatment. Mr. Chamberlain originally intended to obtain an order but there was some delay, and in 1890 the Corporation came in and opposed them. The complaint as to the lighting only referred to the street lighting. If the agreement with the Corporation was *ultra vires* in the first instance then the moral obligation was all the greater, and the company had the more need

Digitized by Google

of the protection of the Board of Trade. The supply of current, he urged, had not been unsatisfactory. Mr. Arthur Chamberlain said Councillor Fell and Mr. Passman (town clerk) were promoters of the original company in Leamington. The original company was established in 1881, and he was asked to take over the company, pay its debts, and start electricity works in Leamington. He agreed that if he found sufficient support in the town he would do so. The letter he wrote to the Council, and which the Corporation had set out in their objections, was that of a business man proposing generally to put his goods before business men. That letter fairly showed what was the position between them. A temporary installation was his idea at the time, with a portable engine and boiler. The support of the Council was the one thing upon which he then relied. The company had carried on the concern for twelve years, and never had a penny interest. They were now turning the corner, and it was proposed to confiscate their property. He should prefer his freedom rather than the Board of Trade should grant two orders. He had previously applied to the Board for an order, and it was not fair to charge him with breakdowns after that application. Mr. J. C. Vaudrey thought the breakdown of the mains was due to accident and could not have been avoided. The present electrical supply at Leamington was capable of meeting any demand upon it, and could be extended to a considerable extent. Mr. F. W. E. Jones, engineer to the company, also gave evidence, and the inquiry closed.

Leatherhead.—The consideration of the electric lighting scheme prepared by Messrs. Handcock and Dykes has been deferred for six weeks. In the meantime the gas company have promised to improve its lighting.

Leith.—The charge for electric current for power purposes has been reduced from 3d. to 1½d. per unit. For lighting purposes a scale of discounts for large consumers is to be drawn up.

Light Railways.—A proposal has been made by a London syndicate to construct a light (electric) railway from Whitehaven, through Workington to Maryport. The company also propose to supply current for public and private lighting at the latter town.

The Board of Trade have authorised the construction of a light (electric) railway from Liverpool to Prescot, and also from the esplanade to the Isle of Wight Railway Co.'s station at Ventnor.

Liverpool.—The following charges for electric current come into operation on April 1:—For lighting 4d. per unit; for power up to 3,000 units per quarter 2d. per unit, for each unit over 3,000 units 1d. per unit; for street lighting 2d. per unit; for lighting municipal buildings, &c., 3d. per unit.

Manchester.—The Electricity committee have received the sanction of the Board of Trade to their scheme for supplying electric current in the districts of Levenshulme, Moss Side and Withington.

Marylebone (London).—The Bill presented to Parliament by the Marylebone Vestry for the acquisition of that portion of the Metropolitan Electric Supply Co.'s undertaking which supplies Marylebone parish, not having complied with the standing orders, has been withdrawn. This is the second Bill presented by the Vestry to Parliament. We fear the ratepayers may come to regard the expense of these proceedings out of proportion to the advantage derived.

Montrose.—Edmondson's Electricity Corporation have acquired a site for an electricity generating station in Blackfriars-street, Montrose.

Newcastle-onTyne.—The Tramways committee have asked Prof. Kennedy to visit Newcastle before his departure to America on behalf of the London County Council, in order that they may have a consultation with him and Mr. Charles Hopkinson as to the system of traction to be adopted on the local tramways.

New Malden (Surrey).—The ratepayers in the Malden and Coombe districts are anxious to obtain a supply of electric current from the Kingston electricity works. It was announced at the last meeting of the Council that the Board of Trade had been seen in connection with the proposed extension of the Kingston mains, and the Board is against extending the scope of the provisional order to include Coombe.

Newmarket.—Electric current was supplied for the first time on the 11th inst. The boilers at the electricity works were supplied by Messrs. Davey, Paxman and Co., the engines by Messrs. Willans and Robinson, the dynamos by Messrs. Thos. Parker (Limited), and the storage battery by the D.P. Battery Co. Current is supplied on the three-wire system, and the capacity of the plant is equal to 3,000 8-c.p. lamps.

Paddington (London).—Owing to the Vestry's objection to certain works proposed to be executed by the Metropolitan Electric Supply Co., under their provisional order (1890), and their Act (1898), the Company appealed to the Board of Trade to appoint an arbitrator, and Major P. Cardew has been instructed to hold an inquiry into the merits of the appeal.

Patent Law in the Soudan.—It has been decided that no registration of trade marks before the Mixed Tribunals of Egypt can be held to protect the rights of their owners in the Soudan.

Proposed Liverpool-Manchester Electric Railway.—The first meeting of the committee recently formed for the purpose of investigating the proposal to construct an electric express railway between Liverpool and Manchester, was held at the Manchester Town Hall on Wednesday, when a sub-committee of twelve was formed to enquire into and report upon the engineering and commercial feasibility of Mr. Behr's scheme. The sub-committee include Sir W. H. Bailey, Mr. William Mather and Ald. Higginbottom, of Manchester, and Messrs. C. Petrie, S. B. Cottrell and A. Bromley-Holmes, Liverpool, an eminently practical group.

Riga (Russia).—It is announced that the Russian Ministry of the Interior has under consideration a project for constructing a network of electric railways in Riga. The Corporation of the town are acting with the Ministry in this matter. It is probable that a loan will be granted the Municipality at low interest to carry out the scheme, which is estimated to cost £160,000.

San Paulo Gas Co.—This company are putting down electric lighting plant for the supply of current to the new passenger stations of the San Paulo Railway Co., and for supplying current for private lighting in San Paulo and district.

Smoke Nuisance.—At Southwark last week the City of London Electric Lighting Co. was summoned for permitting black smoke to issue from the chimney at their generating station at Bankside, on certain specified dates. Mr. Topham, who prosecuted (or shall we say persecuted?) on behalf of the St. Saviour's Board of Works, stated that the Company was recently fined £100 at the Court for similar offences. Mr. Passmore (for the defence) to a witness for the Board of Works: Is it not a fact that your Board would not prosecute were they not egged on by the London County Council? Witness: Originally the County Council did bring pressure to bear, but I do not know anything about it recently. Mr. Pasmore said he did not purpose calling any witnesses, but to frankly explain to the Court how seriously handicapped the company was. Since the case was before the magistrate the company had commenced the work of reconstructing their furnaces, so that of 32 on their premises 18 were now under reconstruction. This had diminished their producing capacity, and they were being threatened by the City Corporation for not supplying current at the necessary pressure. Mr. Slade said he saw no difference between the present case and that previously before the Court, and inflicted the maximum penalty—£10 on each of the six summonses—£60 in all.

Telephone Statistics.—The statistical department of the Swedish Government has recently prepared an approximate list of the number of telephones in use in the different countries of the world, and these particulars are set out below. It will be seen that for Great Britain and Ireland and France the figures are only up to 1894, whereas for Canada the figures include those for 1898. In other cases the figures given are much below those known to us to be correct at a recent date.

	Instruments in use. Number.	Distance covered by lines. Miles.	Kilometres.
Sweden (1897)	56,50)	74,568	120,000
Norway (1897)	20,678	33,481	53,889
Denmark (1895)	10,500	9,321	15,000
Finland (1895)	7,351	13,049	21,000
Great Britain and Ireland (1894)	69,645	83,401	134,215
Holland	8,000	4,971	8,000
Belgium (1895)	9,227	16,235	26,127
Germany (1896)	151,101	147,093	2?6,712
Austria (1896)	21,616	46,375	74,630
Hungary (1896)	10,293	17,940	28,870
Switzerland (1897)	28,846	47,594	76,593
France (1894)	27,736	63,230	101,754
Italy (1896)	11,991	13,049	21,000
Spain	11,038	14,282	22,984
Russia	18,495	40,391	65,000
Roumania	750	141	227
Bulgaria (1893)	300	372	600
Japan (1897)	3,232	5,262	8,468
British India	1,601	2,296	3,695
French India	89	345	556
Philippines	452	592	954

Tunis	200	281	452
Senegal	50	54	87
The Cape and Natal	600	1,100	1,770
United States (1896)	772,627	805,711	1,296,655
Cuba	1,818	1,181	1,900
Canada (1898)	33,500	44,020	70,840
Mexico (1896)	9,000	11,807	19,000
Paraguay (1891)	500	625	1,006
Uruguay (1896)	3,269	8,117	13,063
Australia	823	2,390	3,846
Total	**1,288,163**	**1,509,499**	**2,429,254**

Digitized by Google

Southampton.—Current was switched on to the public lamps on Thursday evening last by the Mayor (Mr. G. A. E. Hussey).

Telephone in Manchester.—The special Telephone Committee of the Manchester Corporation were recently invited to include representatives of that body in a deputation to the Chancellor of the Exchequer from the New Mutual Telephone Co., who are endeavouring to obtain permission to establish a telephone service in Manchester in opposition to the National Company. We have previously referred to the coolness which has arisen between the New Mutual Telephone Co. and the Manchester Corporation, and the final blow has now been given. The special Telephone Committee considers it is not desirable to have the Corporation represented in the deputation.

Ventnor.—It is expected that the electricity works will be in working order by Easter.

Wimbledon.—A charge of 4d. per unit is to be made for current to places of public worship. For public lighting by means of 16 c.p. incandescents a charge of £3 per lamp per annum has been decided upon. The Electric Lighting committee have orders in hand for the supply of about 5,000 8 c.p. lamps for private lighting.

Electro Harmonic Society.—A smoking concert will be held at the St. James's Hall Restaurant (Banquet Room), Regent-street, W., this (Friday) evening at 8 o'clock.

COMPANIES' MEETINGS AND REPORTS.

Direct Spanish Telegraph Co. (Limited).

The forty-seventh ordinary general meeting of this Company was held at the offices, Winchester House, Old Broad-street, on the 17th inst., under the presidency of the Most Hon. the Marquis of TWEEDDALE, K.T.

The MANAGER (Mr. Ch. Gerhardi, M.I.E.E.) read the notice convening the meeting and the minutes of the last meeting.

The CHAIRMAN then said: Gentlemen, it is now my duty to invite your approval of the report and accounts, which I presume you will take as read; and in doing so I propose to supplement the report, which is already very full of information, with a few remarks on our proceedings during the past year. The traffic receipts show an increase of £3,812, owing almost entirely to the exceptional state of things which prevailed in the Spanish colonies during the past year. This condition no longer exists, and the traffic has now fallen back to its normal state; and I may mention with respect to this that the decline is somewhat considerable, amounting up to date to about £891, although, in fact, the number of telegrams is very much greater, showing that we are dealing with normal traffic. During the time of the Spanish war we had long official messages and very long press messages, which went to swell our receipts very much. Of course, this has all come to an end, and we shall now have to look forward to somewhat reduced receipts. The ordinary expenses exhibit an increase of £349, which is explained by the increased traffic, the items composing it—such as a larger staff, more instruments, &c.—being such as are dependent on the maintenance of the traffic and the work performed. On the other hand, there is a considerable decrease, amounting to £153, on the London office and London station expenses, as well as a small decrease of £33 under the head of travelling expenses. The extraordinary expenditure is higher by £3,082 than it was in 1897, and this is due to the cost of the two repairs to the Bilbao cable, amounting to £2,117, and to that of the extension and alteration of the London station, amounting to £961—making, together, £3,078. With respect to this latter item, I am sure that the shareholders will have noted with satisfaction that excellent accommodation has now beeen provided by the acquisition, upon a long lease, of 75, Gracechurch-street. This will enable the Company to carry on its business with greater advantage both to the public as well as to the staff. The terms on which the parts of the building not required by the Company have been let by the Company to desirable tenants will render the rent to us extremely reasonable. There is also an item of £326 which requires explanation. That is for the cost of renewing the two submarine cables across the Helford river, which form part of the duplicate underground line between Falmouth and Kennack, where the Bilbao cable lands, and which, after working for 17 years, failed entirely during last year. The item in the extraordinary expenses which shows the largest increase, £498, is explained by the necessity of renewing the underground lines at Bilbao. The Company's station in the town of Bilbao is connected with Arrigunaga, the landing place of the cable to England, by underground cables. These were laid in 1882, and in many places had become very defective, owing to the nature of the soil and other causes. It was therefore decided to replace the worst sections, before the cables failed entirely, by pipe lines. This important connection is now in fairly good order, although it is not at all improbable that before very long we may have to renew further sections of these underground cables. Another item is £11 for the supply and fitting of Hughes' instruments at our Bilbao station. The Spanish Telegraph Administration urged the adoption of the Hughes' instrument in working the special wire between Bilbao and Madrid, and as it was found to be to our interests to accede to their wish, the necessary instruments were purchased. The communication between Bilbao and Madrid has been considerably improved by their use. The Morse instruments can however, be resorted to at any time on the Madrid-Bilbao wire when through communication between Madrid and London is required. Paragraph 4 of the report refers to a fault which was discovered on May 21 last in the Bilbao cable about 13 miles from Bilbao. This fault was not serious enough to interrupt communication, but it rendered duplex working difficult, and as there happened to be a repairing ship of the Eastern Telegraph Co. on her way from Lisbon to England, the opportunity was taken advantage of to remove the fault. Two months afterwards the Bilbao cable gave way altogether, at 199 knots from Falmouth, owing to the cable lying upon uneven ground. This repair was effected, and after soundings had been taken, the position of the cable was altered, and it is hoped and believed that we shall not experience any recurrence of such an accident. The repair of this cable is remarkable for the promptitude with which it was effected. The break occurred on July 8, and although the steamship "Mirror," commanded by Capt. Pattison, was then in the Thames, the repair was effected within six days. That reflects considerable credit on Capt. Pattison, who is a most expert cable engineer. The net result of the year's operations is that, after providing for the debenture interest and redemption, and placing £5,000 to the reserve fund, the Directors are able to recommend the payment of the usual dividend of 10 per cent. on the Preference shares, and of a dividend at the rate of 4 per cent. on the Ordinary shares, half of which has already been distributed. The reserve fund now amounts to a little over £50,000—a substantial sum, no doubt, but still, in our opinion, not adequate as a provision for future contingencies. The only criticism that has reached us with reference to the report is that our dividend is not quite as large as might have been expected. I think, however, what I have said about the falling off in the traffic receipts this year, and their return to a normal condition, affords very good reason for not increasing our present dividend of 4 per cent. If we thought it was probable that we should be able to maintain a dividend of 5 per cent., if we were to pay it, I think that we should have no hesitation whatever in recommending a somewhat larger dividend; but in view of the reduction in the receipts and the improbability, therefore, of our being able to maintain a dividend of 5 per cent., supposing we were to pay it now, we feel that it will be better to strengthen our finances by adding to the reserve and contingency funds, and continue to pay the not at all small dividend of 4 per cent. With these observations I beg to move—

"*That the Report and accounts now presented be and are hereby received and adopted.*"

Mr. J. DENISON-PENDER seconded the motion, which was carried unanimously.

The CHAIRMAN: I have now to propose—

"*That the dividend at the rate of 10 per cent. per annum, less income tax, on the Preference shares, and a dividend of 4 per cent. per annum, free of income tax, on the Ordinary shares, both for the half-year ended Dec. 31, 1898, be and are hereby declared.*"

Mr. PENDER seconded the resolution, which was unanimously adopted.

On the motion of the CHAIRMAN, seconded by Mr. F. ALEXANDER JOHNSTON, Mr. J. Denison-Pender was re-elected a Director of the Company.

The auditors, Messrs. Deloitte, Dever, Griffiths and Co., were afterwards re-elected to their position for the present year.

A vote of thanks to the Chairman and Directors was then passed, and the proceedings terminated.

British Electric Traction Co. (Limited).

The third ordinary general meeting of this company was held on Saturday last, Sir CHARLES RIVERS WILSON, G.C.M.G., C.B., presiding.

The SECRETARY (Mr. George Stevens) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, when I last addressed you I predicted that the balance-sheet which we should present to you on the present occasion would show the Company to be in a very strong position. That expectation has, as you will agree, been realised. Our year has been one of very considerable labour, accompanied by certain anxieties, and we have had to encounter great obstacles; but we have accomplished a good deal, and I think we may consider that we have prepared the ground for a series of large and, I trust, very successful operations for the future. The report and accounts, I presume, we may take as read. I think it will be satisfactory to you that at the end of the second year of our operations we are able to show a substantial net profit of £67,778; and you will bear in mind that, although this includes £9,804 brought forward, it does not include premiums received on new issues of capital. With reference to the proposed appropriation of this net profit of £67,778, the Directors propose to write off the remaining portion of the preliminary expenses, £5,879. It is not generally the case that a company is able to wipe out the whole of its preliminary expenses within the first two years of its existence, but I think it is admitted that, whenever it is possible, it is a good thing to get this item without delay. The goodwill account stood last year at £15,000 and we propose to write off £5,000, leaving it at £10,000. You will remember how the goodwill account of £15,000 arose. At the inception of the Company £5,000 was paid as profit to the Pioneer shareholders and the other £10,000 for the promotion of the Company. They were not excessive figures, having regard to the very valuable business which has been built up upon the foundations thus provided. As a matter of fact it was really absurd, for the goodwill of a company like this to be put at so low a figure as either £10,000 or £15,000, and instead of the goodwill account being required to be written down, it would be really more correct to write it up; for if the goodwill of the business was worth £15,000 at the time of the formation of the Company, I have no hesitation whatever in saying that it is immensely more valuable than what is represented by that figure. Nevertheless it is the desire of the board to eliminate from the balance-sheet all items that are not immediately realisable, and as there is no object in

Digitized by Google

debiting the goodwill account with £15,000 when, as a matter of fact, it is represented by a very much higher figure, the Directors propose gradually to wipe it out of the balance-sheet. In speaking of the goodwill, the shareholders will realise that an enormous amount of work has been done which is not represented in the accounts at all. The Company has not only made a satisfactory profit, but it has built up a great organisation, which will serve the purpose of creating and carrying on a large business in the future, and has laid the foundation for many profitable transactions. Although the business has been established only so short a time, we have collected around us a staff of competent officers, and machinery for carrying out a large amount of engineering and other work, all of which is worth a considerable price, but which is not in any way brought into the accounts. The whole expense of developing the business has either been charged to revenue account or has in part been added to the cost of undertakings in hand, all of which will come back to us with a profit. We have, of course, to provide for the dividend on the Preference shares for the year. £1,195 was paid as interim dividend on Aug. 15th last, and £2,252 is the proportion of the Preference dividend calculated up to the end of the year. This leaves £53,451 to deal with. As the proposed dividend of 6 per cent. on the Ordinary shares for the year would absorb only £18,000, leaving £35,451 to be carried forward, some shareholders may think that we have erred on the side of prudence, and that we ought to distribute a larger dividend, but I will say at once that the board have given this matter their most anxious consideration; and while they are quite satisfied that the profits have been fully earned and that if we could be quite sure of the future there would be no objection whatever to a somewhat larger distribution, yet, in view of the fact that we are developing a very large business, and one which is not altogether free from uncertainties, we think it would be wiser for us to make it our first object to put the Company in a thoroughly sound and impregnable financial position. We are working largely for the future. The full development of this business requires large increases of capital, and the stronger our position is, the better will be the terms upon which we can raise this capital, and the higher will be the dividends that we hope to be able to distribute on the Ordinary shares. You will see by the accounts that the charge for dividends in respect of the past year was only £21,448, whereas in the current year, upon the capital actually issued, without taking into consideration the charge which may arise in respect of future issues, will be £46,000. I refer to this in further explanation of the reason why we think it well to carry forward the balance of £35,450. We also think it very desirable that we should at least equalise our dividends in the future, irrespective of any increase. Turning to the capital account, you will gather from the report that the whole of our share capital and £200,000 debenture stock, making £800,000 in all, have been issued up to date. At the end of the year only £500,000 had been issued, and the net amount of premiums received was £29,135, which we have invested in consols. Since the close of the year a further £300,000 of capital, part of the total of £800,000, has been issued, and these additional issues have produced premiums of about £45,000. We have, therefore, at the present moment a reserve fund of something like £75,000, and it is the intention of the Board to invest this reserve fund in consols and first-class securities. Now that the whole of our share capital has been subscribed and is profitably employed in the business of the Company, the Directors consider it advisable that the shareholders should give them the necessary power to make further issues as and when they may deem advisable. The proposal is to double the present share capital, which will give the Directors power to double also the present issue of debenture stock. It would be impossible for me to explain in detail all the large number of undertakings we are engaged upon. The list embraces undertakings from Devonport, Poole and Brighton in the south, to Greenock in the north; and there is scarcely a division of the British Isles in which the Company is not carrying on its operations. Some of these are of considerable magnitude. To take the Potteries Electric Traction Co. as a sample, it has a subscribed capital of £400,000 and is carrying out electrical tramways and light railways extending over a distance of 34 miles. This is certainly the largest electric traction undertaking in the country. Then we have the Swansea undertaking, which has a subscribed share and debenture capital of close upon £200,000, and is at present working authorised tramways and has also obtained statutory powers for converting these tramways to electrical working. Quite lately an arrangement has been made to take over the Swansea Mumbles Railway, which will also be electrically equipped, and passengers will be enabled to travel from any part of Swansea right to the Mumbles by electric car without changing. I may also take the Dudley-Stourbridge Company which is part of the large scheme of electrical tramways we are endeavouring to provide for the whole of South Staffordshire, and that part known as the "Black Country," a combination similar to that which we are carrying out in the Potteries district. The Dudley-Stourbridge Company has a subscribed capital of over £60,000, and this will shortly be increased. These are examples of the work we are doing. With regard to the Company's investments, by far the largest part of our capital is invested in debentures and shares in associated and other companies, and it is important that you should feel satisfied that these investments are sound and remunerative; and when I tell you that they cover a list of no fewer than 40 companies, you have no cause to fear that we have put all our eggs into one basket. Every one of our investments is a satisfactory source of profit. It is, however, not so much at present for the sake of investment that we put our money into these companies, but rather with a view to develop electric traction and the business of our Company. One of the difficulties this Company has to overcome is the antipathy of shareholders in the existing tramway companies to sanction the conversion of their line to electric traction. We have, first of all, to teach the existing tramway companies that it is in their interests to adopt electric traction, and when we have succeeded in doing this we have to approach the local authorities and persuade them to allow electric traction to be adopted. In each case we are met with some misgiving and suspicion, and, in the case of the local authorities, we are brought face to face with the difficulty presented by the present tendency of municipalities to undertake trading operations. They have not the enterprise or the initiative to propose electric tramways, but directly we approach them with a proposal to improve the service of the tramways in their towns, or with a proposal to provide additional tramway facilities, it at once occurs to them that we, being a commercial body, would not make these proposals if they were not likely to be profitable; and then they want to know why, if profit is to be made, they, the municipalities, should not make it themselves. But they do not know how to go about the business, and they do not hesitate to negotiate with us (to "pick our brains," so to speak), and then, when we have told them all we can tell them, they frequently decide in favour of a policy of what is generally called municipalisation, and they do so on the ground that it is in the interests of the ratepayers; but the curious thing about this cry of municipalisation for the benefit of the ratepayers is that in most cases where corporations have thus municipalised commercial undertakings, the rates do not go down, but, on the contrary, are steadily increasing. On a former occasion I pointed out the difficulties which corporations have in municipalising tramways and light railways when worked by electricity, because they require to be carried beyond municipal boundaries; and our further experience of these difficulties has convinced us that, if the development of this enterprise in this country is to be in the hands of local authorities, we shall never have the tramway and light railway facilities which other countries possess. I may add, *apropos* of this important question, that we do not propose to confine our operations entirely to England, Scotland and Ireland; but we are looking outside these islands, and hope to obtain some position in connection with profitable undertakings in foreign countries, or, still more probably, in some of our colonies. There is no reason why we should not undertake that work if profitable; but I insist on it, in connection with the question of the opposition we encounter from local authorities, as a sort of object-lesson showing how the policy of those bodies has a tendency to drive British enterprise and capital out of this country. Reverting to the question of investments, all our investments stand in the books at cost price, and in the case of the shares mentioned in the auditor's certificate, which cost us £10, they are now saleable in the market at £16, and others are at even a higher premium. We propose in the future to make up the accounts to the end of March in each year. This will enable us to include in our profit and loss account the results of the year's working by the various associated companies, and we shall be able to embody in our report, the reports of the various associated companies in which you are interested. The next account will, therefore, be for a period of fifteen months, and the next ordinary general meeting will probably be held some time in May next year. I now move the adoption of the report and accounts, and of the recommendations as to dividends and otherwise.

Mr. EMILE GARCKE seconded the motion.

Mr. TUCKETT thought the statement the chairman had made showed the position of the Company to be eminently satisfactory. Of the £200,000 capital issued last year £100,000 was in Preference shares and £100,000 in Debenture stock. On those amounts £41,000 gross was received in premiums, and £29,000 net. That was £11,000 went for expenses of issue, or rather more than 5 per cent. He did not suggest that that was an improper or an unnecessary expense, but the Company now stood in such a sound position, and the shareholders believed in its prospects so thoroughly, that they would now be glad themselves to take the issues of capital that might be made.

Mr. MAKINS asked if they could have half-yearly meetings or, at any rate, an interim report from the Directors. The Company had no traffic receipts to publish, like the great railway companies, and he thought what he had suggested might be done.

The CHAIRMAN: There are reasons which I think will commend themselves to all which would rather conflict with the too frequent publication of the results of our operations. There is very strong competition in the matter of electric traction, and I think it is unnecessay to take the entire public—and particularly that portion of the public which may be in competition with us—into our confidence regarding our transactions. If at any time any shareholder desires information the offices are open, and the best attention of the officials shall be given to them.

Mr. CORK wished to know in what way their Company took a part in the administration of the companies with which they were associated.

The CHAIRMAN: The way in which we exercise control over those companies is by obtaining a majority on the Board, and sometimes the whole control is in our hands—by our being represented by our own Directors or officers. We, therefore, have the complete control, if not the entire management of those undertakings; and I would also mention this—that on appointing our officers and Directors to act as administrators in these companies, we do not allow them to receive any fees or remuneration for their services. Whatever fees are received are paid into the treasury of this Company.

The resolution for the adoption of the report and accounts was then adopted.

Lord Rathmore and Mr. J. S. Raworth were re-elected Directors, and Mr. F. W. Smith was re-appointed auditor; after which an extraordinary meeting was held, at which

The CHAIRMAN said: You will understand the necessity of our obtaining further capital shortly, and the amount we ask you to give us the discretion to issue is 60,000 shares—that is to say, 30,000 Ordinary and 30,000 Preference shares.

A resolution, approving the issue of the additional capital, was proposed.

Mr. MAKINS proposed an amendment that all new shares should be offered to the shareholders in proportion to their holdings.

The CHAIRMAN said: It would be quite impossible for the board to accept such a resolution as a binding instruction. To impose upon the

Digitized by Google

board a standing obligation under all circumstances, without any reservation of their discretion, is a matter which would certainly not be advisable in the best interests of the Company. Our financial friends have done much for us up to the present time. I am not at all hostile to the practice which Mr. Makins has indicated, but I consider that its application as an obligation on us is at the present time premature, and would be most improper and most harmful. It might place us in the greatest possible difficulty. A question has been asked as to whether it was the case that one of the Directors was connected with the board of the Electric and General Investment Co. It is perfectly true that one of our members—the most distinguished member of our board I may call him, and to whom you owe almost exclusively our extremely successful results—is a Director of that Company. For a long time before Mr. Garcke joined this Company he was a member of the board of that Company, and the very fact that he is a member of that board has been of the utmost advantage to your interests. I wish to speak within bounds, but I felt indignant that such an observation should have been made, implying distrust, and something more, of Mr. Garcke, whose labour in your interest I have no words to describe. I assure the gentleman who made that inquiry that he would not have done so had he known what Mr. Garcke is and what Mr. Garcke has done for this Company, which is, in a sense, his sole creation. The benefit which has accrued to you from the enhanced value of our securities you owe, in a large measure, to Mr. Garcke.

Mr. MAKINS said he desired to state that he had not cast any imputation on Mr. Garcke. He knew that gentleman's ability, and estimated it as highly as anyone could. The only point he had raised was that the outside public had been employed to take an issue of Preference shares, which the shareholders in the Company would themselves have been delighted to take up. He himself applied for 500 shares and received only 100. He desired to withdraw his proposal.

This course having been allowed, and the notion of the issue of additional capital unanimously approved, a vote of thanks to the Chairman and Directors terminated the proceedings.

South London Electric Supply Corporation (Limited).

The ordinary general meeting of shareholders in this Company was held at Winchester House, Old Broad-street, on Tuesday, Mr. GEORGE ELLIS, J.P., presiding.

The SECRETARY (Mr. Sidney H. Webster) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, in greeting you at this second annual meeting, I do so with the utmost confidence, as I feel that our financial policy has proved to have been based on thoroughly sound and business principles, and has consequently been of immense advantage to the Company. In fact, had we not seized the opportunity which presented itself of placing the balance of the share capital when we did, we could not have carried out the contracts in their entirety, or have built a station and erected plant of sufficient capacity to enable us to satisfactorily supply the very extended area over which we have powers. Now that we have had time to realise the magnitude of the work we have undertaken, and the possibilities of the demand for electric energy in the parish of Lambeth, entailing, as it does, miles and miles of mains, and the great outlay necessary for the erection and equipment of so large a combined generating station and dust destructor as we are building—the largest, I believe, in the United Kingdom—I think we have reason to congratulate ourselves upon our strong financial position. It is very satisfactory to feel that after meeting all the charges incumbent on us for this very large station we shall have ample trading capital, and be able to start business on a thoroughly sound financial basis. I will now briefly explain to you the progress we have made, and the condition, as it stands to-day, of each department of our work; that is to say: (1) the buildings and the work generally upon the site; (2) the mains, transformers and house connections; and (3) the plant and machinery. First as to the buildings and the work upon the site. You will recollect that owing to difficulties and negotiations in connection with the acquisition of the site, it was not until Michaelmas of 1897 that we were in actual possession of the land, so that, what with the time taken up in getting building materials on it, and organising the labour, it was not until November in 1897 that the contractors were able to commence the actual construction of the buildings. During the spring and summer months of 1898, the weather was most favourable for building operations, but this was succeeded by several months of broken and wet weather during which the builders were much impeded, being only able to work about two-thirds of the time. Lately, again we have had very favourable weather and the work has been carried on with great speed. The position to-day is, that the chimney shaft, 180ft. in height, is quite complete and ready for use. The main building, consisting of the destructor house, boiler house, engine and dynamo house, is finished and roofed in, and the various rooms adjoining the main building, consisting of coal and other stores, outbuildings, &c., are also finished. The offices are ready for occupation, being quite complete with interior fittings and furniture, so that in a few days—in fact, on the 25th inst.—we shall remove our clerical and engineering staff into them, and by thus having all the officers under one roof much labour and inconvenience, and consequently expenditure, will be saved. The whole of the boilers have been delivered and erected, and four of the boilers and eight of the destructor cells are finished and ready for use; whilst the progress being made on the remainder makes it certain that the whole of the work within the destructor and boiler house will be finished by the early summer. The artesian well alluded to in the report is finished and is 390 feet in depth, and in this connection I should like to say that the Board are extremely gratified, as I feel sure you are, at the success which has attended this venture, for I must call it so. We took a considerable time in deciding as to whether we should spend the necessary amount—roughly £1,000—for the experts whom we consulted on this point were not unanimous in their opinion as to whether we should obtain an abundant and, what is more important, a permanent supply. However, the water we have struck has proved to be flowing from a true fissure vein in the chalk, and will be ample for all our requirements. Secondly, as to the mains, transformers and house connections, the map before you will enable you to judge of and to realise the amount of work done, and you will, I feel sure, admit that good use has been made in this branch of the time we have had at our disposal. The progress made by the British Insulated Wire Co. in the laying of mains during the past year has been most satisfactory. Mains have now been laid in a total of over 22 miles of streets. Earthenware conduits to carry high tension cables have been laid for sufficient length to carry over 44 miles of high tension cable. Twenty-four miles of low tension distribution cable have been laid on the solid filling-in system and brought into use, and over 13 miles of high-tension feeders have also been drawn in the before-mentioned ducts and brought into use. The above work has involved the excavation and making good of 25 miles of streets. From these mains 220 connections to consumers' houses have already been run, and, of course, meters erected and connected up in each case. Thirdly, as regards the plant and machinery, I am sorry I cannot report to you quite so favourably with reference to these items; but, as many of you are, doubtless, aware, the late strike in the engineering trade has caused quite a congestion in this field of work. English manufacturing firms are so far quite unable to make up the time lost owing to that unfortunate strike. To such an extent is this the case that even some of our largest railways have reluctantly been compelled to place their orders for locomotives abroad—for the most part in the United States of America. As you are aware, we have been taking on consumers and supplying them with energy by means of connecting our mains to those of a company who have a generating station in a district adjoining ours. Of course, this has not been done without incurring some additional expense, but we consider that we are amply compensated for the cost involved, for we have by this means been enabled to take on consumers with a total number of 15,870 8 c.p. lamps already, which will enable us to employ our machines directly they are ready, and thus avoid the great loss which generally occurs after the opening of an electric light station, while waiting for customers to get their premises wired. This should be most satisfactory to our shareholders, as if such a large number of consumers can be obtained before the works are opened, there must be every prospect of a large and lucrative business in store for us. We have not made any great effort in procuring customers so far, for there have been difficulties and troubles in supplying them under these conditions, which we trust will not occur when we are in a position to supply direct from our own station, and moreover we have not been able to deliver current, except to a limited area of our district. I do not know that I have any other point on which you may wish to be informed, but if any shareholder wishes to ask any question I shall be happy to reply. I now move the adoption of the report and accounts.

Mr. W. W. PHIPPS seconded the motion.

Mr. BARRETT asked what was the earliest date at which they expected to have their central station completed and be giving the supply from their own machinery? He thought that it would also be very interesting if the shareholders could hear whether they expected to have a load of 50,000 lamps by the autumn, and if so, whether they thought that that number would justify the Board in paying a reasonable dividend—say at the end of the financial year? Also was arc lighting likely to be adopted by the Vestry; was there likelihood of a day load from the supply of current for power purposes; and was it certain the Company had a monopoly of electric supply in their district?

Mr. A. TOOTH asked when the next call was likely to be made, and whether the houses they supplied were few and far between or close to the station.

The CHAIRMAN, in reply, said: In reply to Mr. Barrett, I may say that we anticipate that our station will be ready to supply current at the end of May, or at the beginning of June. That does not mean that we shall then have sufficient available from our own machines for the winter, but we shall get some engines in the summer, and others will follow about July or August; and we quite expect to have an abundance of plant for our requirements next winter. Mr. Barrett has also asked me one rather difficult question—namely, whether we can pay a dividend on a load of 50,000 lamps? In answer to that I can only judge from my experience in another place. I found that the supply in the second year came to 100 per cent. more, or double the quantity we had in the first year, and that in the three years which have since elapsed we have had an increase of 25 per cent. every year. You asked, I think, when the prospect of a dividend will arise. If I tell you what has happened with some of the chief companies in London you will be able to form your own opinion. The Westminster Company paid at the end of 2¾ years; the House-to House Company not for 10 years; the Pall Mall and St. James's Co. in 2¾ years; the Kensington and Knightsbridge in 3¾ years and the Notting Hill Company in 5 years. I hope that we shall not have to wait as long as the longest of those dates, but I do not think that we shall quite come up to the earliest. You have mentioned the question of arc lamps. That is a very important point, because I know by long experience that wherever you put the arc lamp the public will have the incandescent. They follow each other directly; the arc lamp seems to act as a magnet in attracting the incandescent. We, however, have no power in this matter unless we get an order from the Vestry. I have myself been several times to the Vestry about it, but I have not been able to induce them to adopt the arc light. We, have, however, one thing in our favour which may induce them more than anything else to adopt the arc lamp, that is, that the boundary of the parish of Newington is in the middle of a street in our area of supply, this boundary dividing the two parishes. The parish of Newington has decided on adopting the arc lamp, and part of the street in question

Digitized by Google

which is in that parish will be lighted up in the course of a few months; and I feel certain that if the parishioners of Lambeth see one side of the street lighted by the electric light and the other side by gas, they will very soon demand the electric light. If not, I can only say that they are very different from the people in the south of England. I do not know if we shall be able to get a day load. On the other side of the river, I know that there is a considerable day load, but I have seen but little as yet to lead me to expect the same thing in the south of London, With regard to the question, as to when the next call will be made. I may say that we have sufficient money in hand to carry us up to the middle of May; and, therefore, the next call will be about the middle of May or the beginning of June. I think the same gentleman asked whether the lights were very much scattered. Ours is a very large area, and in that way our supply may be said to be scattered, but the consumers are in clusters. We generally find when we get a customer for the light that his next-door neighbour also wants it. I think that we supply more private houses than shops at the present time. As to our having a monopoly, that must be so, because this Order was granted by the Vestry. They cannot get another Order themselves, and no one else would get one, as in that case they would also have to purchase our undertaking at the end of the term. I therefore think that you may consider that ours is an absolute monopoly.

Mr. PEARSON inquired what powers the Vestry had as to taking over the Company's undertaking.

The CHAIRMAN: They can re-purchase it at the end of 21 years, but in that case they must pay us a profit of 25 per cent. over the capital expended. They can obtain it at par at the end of 31 years.

The motion was carried unanimously.

Mr. Phipps and Mr. Algernon Turnor, C.B., were re-elected Directors, and Messrs. Price, Waterhouse and Co., were re-appointed as auditors.

Mr. PEARSON afterwards proposed a vote of thanks to the Chairman and Directors for their services. He had been in the City for 35 years, and had never before seen a balance-sheet of a company showing a profit before its works were opened. He would like to include in the vote their courteous Secretary.

Mr. BARRETT seconded the motion, which was carried unanimously.

The CHAIRMAN acknowledged the vote, and the proceedings terminated.

Willans and Robinson (Limited).

The tenth half-yearly report of the directors of this company, covering the period to Dec. 31 last, states that, after writing off as depreciation £5,013. 3s. 4d., and paying interest upon Debenture stock, the balance to credit of profit and loss account (including £2,441. 6s. 11d. brought forward) is £25,069. 14s. 3d. The directors propose that dividends be paid at the rate of 6 per cent. per annum upon the Preference shares, and at 10 per cent. per annum upon the Ordinary shares, together amounting to £12,000. The amount payable to the original directors is £3,863. 10s. 2d., leaving £9,206. 4s. 1d. The directors propose to carry £2,000 to Debenture redemption sinking fund, and £3,500 to reserve, leaving £3,706. 4s. 1d. to be carried forward. The balance of £11,124. 14s. 6d., standing in last accounts to credit of the share premium suspense account, has been disposed of by writing off £163. 12s. 7d. removal expenses, £3,368. 6s. 8d. off value of freehold works at Thames Ditton, and £1,606. 7s. 10d. off sundry items of plant at Thames Ditton. £986. 7s. 5d. is kept in hand in a removal suspense account, and £5,000 has been carried to reserve.

As the period of the accounts now presented corresponds with the conclusion of the fifth year of the company's working, it may be pointed out that the sums reserved out of profits in the five years, viz., £25,146. 9s. 11d. reserve fund, £10,000 debenture redemption fund, and £3,706. 4s. 1d. now carried forward, amount together to £38,852. 14s., and that this sum exceeds the amount paid for the goodwill of the business.

The last year, and more particularly the last half-year, have been marked by a great increase in the demand for the special class of machinery which the company manufactures. There has also been a rapid increase in the size of the engines. Twelve months ago it was announced that an engine was on order to develop as much as 1,500 H.P.—a notable advance upon the sizes previously made by the company. Six months later the number of such engines on order had increased to four; the number now on order is 16, and there is reason to expect that much larger sizes will be called for.

The directors believe that the increased demand for engines, and especially for large engines, is due to permanent causes, and that it will continue to increase to an extent far exceeding the present producing powers of the company's plant. They also believe that if the company becomes unable to accept the orders offered to it, they will pass into the hands of foreign competitors, with permanent injury to the reputation of the company and to the interests of the shareholders. The directors are, therefore, of opinion that the plant should be increased, and that larger and more powerful tools should be provided. The directors also consider that the manufacture of the Niclausse boiler should be taken up on a larger scale than has hitherto been contemplated, or than is possible at Rugby. Under these circumstances the directors propose to take the existing boiler shop at Rugby as an additional machine shop, and to make some other additions, adding in all about 60 per cent. to the space now available for machine tools; they also propose to double the size of the foundry. They propose to erect separate boiler works upon a site which has been secured near Chester, upon the river Dee, with the advantages of cheap sea carriage for materials, and easy railway communication with Rugby and other important centres. The scheme will render necessary an increase of capital, and resolutions will be submitted to the forthcoming meeting authorising the creation of 40,000 new shares of £5 each, for one-half of which the directors propose to invite subscriptions in the course of the ensuing month. Subject to the concurrence of the existing Preference shareholders, it is proposed to take power to issue half the new shares as Preference and half as Ordinary.

County of London and Brush Provincial Electric Lighting Co. (Limited).

The report of the directors of the above Company for the year ended December 31st is as follows:—

Capital.—The capital expenditure in respect of the Company's London districts amounted to £148,767. 16s. 2d., making the total £562,587. 6s. 2d. This expenditure was met mainly by the balance of instalments falling due on the 10,000 Ordinary shares.

Revenue.—The net revenue, including balance from last account, and after payment of proportion of rents, rates, taxes, interest, and general establishment charges, is £17,375. 18s. 6d. Out of this an interim dividend on the 6 per cent. Preference shares for the half-year ended June 30th has been paid, and the dividend balance for the half-year just ended is recommended. This will leave £5,775. 18s. 6d., which it is proposed to carry forward. Nothing is included for the considerable increase in value that has taken place in the Company's investments, which stand in the balance sheet at cost. The Company is promoting a Bill in Parliament to enable the Company to obtain compulsory powers for acquiring lands and securing rights of way for the purpose of connecting its various London districts, as authorised by the special resolution approved by the shareholders.

The Directors have appointed Mr. Joseph Shaw to a seat on the Board to fill the vacancy created by the retirement, in 1896, of Mr. W. C. Braithwaite.

The following particulars relating to the Company's London stations accompany the report:—

St. Luke and Clerkenwell and Eastern Holborn.—The net revenue for the twelve months to December 31st last amounted to £2,158. 13s. 2d. In these districts the total applications to December 31st, including power, represented the eqivalent of 43,599 8 c.p. lamps, of which 36,303 were then connected. The applications for the year represented an increase of 18,769, and the connections 12,456. At the same date 35 users of motors aggregating 128 H.P. were supplied from the mains, and further applications have since been received raising the total to 60 representing 273 H.P. To meet the growing demand for power, special plant for the generation of continuous current, capable of supplying 1,500 H.P., is in course of erection, which will make, with the power plant already at work, an available total of 2,000 H.P.

Western Holborn and St. Giles.—The laying of mains in this district has been commenced, and a supply of energy, both for lighting and power purposes, will be available at an early date. The Company also holds orders for Mile End Old Town, St. George's-in-the-East, and the district of the Limehouse District Board of Works, all of which it is intended to supply from the City-road station.

Wandsworth District.—The net revenue for the year to December 31st amounted to £4,958. 18s. 11d. Applications for the equivalent of 32,636 8 c.p. lamps had been received at December 31st last, of which number 28,914 were then connected. The increase in lamps applied for during the year was 15,802, and in lamps connected 15,007.

Camberwell.—The street work in this district has been unavoidably delayed, but it is expected that supply will be available by June, a right of way through Lambeth having been obtained. The equivalent of 3,041 8 c.p. lamps were applied for at December 31st.

St. George-the-Martyr.—The work of laying mains in the compulsory streets in this district is in progress, and supply of current will be commenced at the same time as in Camberwell.

St. Olave.—The works in this district will be commenced forthwith.

[The Company's interests in (1) the Bournemouth and Poole Electricity Supply Co., (2) the Dover Electricity Supply Co., and (3) the Richmond (Surrey) Electric Light and Power Co. have been recently reported fully in *The Electrician*.]

NEW COMPANIES, STATUTORY RETURNS, &c.

DAVIS AND TIMMINS (LIMITED).—This company was registered on March 17, with a capital of £110,000, in £1 shares (60,000 £6 per cent. cumulative Preference), to acquire and take over as a going concern the business now carried on by Davis and Timmins (Limited), and to carry on the business of engineers, screw manufacturers, metal turners, &c. The first directors are:—Sir Henry C. Mance, C.I.E., H. Benbow, E. Davis. A. Le Neve Foster and G. E. Davis.

FRESHWATER AND TOTLAND (I. W.) ELECTRICITY SUPPLY CO. (LIMITED).—This company was registered on March 11, with a capital of £15,000, in £1 shares, to form centres at Freshwater and Totland, Isle of Wight, or elsewhere, for the generation of electric light and power, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in electrical apparatus, generators, accumulators, lightning conductors, lamps, fittings, &c. The first subscribers, with one share each, are: W. S. Nicholson, J.P., Lieut.-Col. R. G. Temple-Cotton, A. Bayliffe, A. Hollins, M.D., C. H. Hands, M.B., J. Dover and W. J. Waterhouse. The first Directors are: William S. Nicholson, Lieut.-Col. R. G. Temple-Cotton, and A. Bayliffe.

INTERNATIONAL TELEPHONE MANUFACTURING CO. (LIMITED).—This company was registered on March 1, with a capital of £200,000, in £1 shares, to manufacture telephones and telephone appliances, to establish, work, manage and regulate telephone exchanges and electric lighting works, and to carry on the business of a telephone, telegraph, and electric light, heat and power supply company, and of electricians, electrical and

Digitized by Google

mechanical engineers, electrical apparatus manufacturers, &c. The first subscribers are: C. Cowley, A. E. Cowley, H. D. J. Claxton, C. E. Craig, J. D. Haddock, J. H. Todd and W. H. Sinclair.

AMAZON TELEGRAPH CO. (LIMITED.)—The annual return to Feb. 10 gives the capital as £250,000 in £10 shares, the whole of which has been taken up and paid for in full.

CAMBRIDGE ELECTRIC SUPPLY CO. (LIMITED).—According to the annual return to Feb. 17, the nominal capital is £100,000, in £10 shares, of which 9,423 have been taken up; £8 per share has been called on 4,970, and £2 per share on 4,453.

EASTERN TELEGRAPH CO. (LIMITED.)—The annual return to Feb. 2 has been filed. The capital is £6,000,000 stock, divided into £4,000,000 Ordinary and £2,000,000 Preference. £5,795,263 has been taken up and paid for in full.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING CO. (LIMITED).—The 1899 return of this company has been filed. The capital is £350,000 divided into 50,000 Ordinary, 10,000 First Preference, and 10,000 Second Preference shares of £5 each. 15,000 Ordinary, 10,000 First Preference, and 6,687 Second Preference shares have been taken up, and 5,000 Ordinary shares have been issued as fully paid. The full amount has been called on the others.

NATIONAL ELECTRIC SUPPLY CO. (LIMITED.)—The annual return to Feb. 22 has been filed. The capital is £84,943. 15s., divided into 9,050 Preference shares of £5 each, 10,850 Ordinary shares of £3. 12s. 6d., and 100 Founders' shares of £3. 12s. 6d. each. 1,000 Preference and all the others have been taken up, and the full amount has been called.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING CO. (LIMITED).—According to the annual return to Feb. 28, the capital is £100,000, in £10 shares, of which 9,918 have been taken up; £8 per share has been called on 5,000 and £5 per share on the remainder.

NORTHAMPTON ELECTRIC LIGHT AND POWER CO. (LIMITED).—The annual return to March 9 has been filed. The capital is £50,000, divided into 10 "A" and 49,990 "B" shares of £1 each. 10 "A," 17,288 "B" Ordinary and 7,000 Preference shares have been taken up. £1 per share has been called on 10 "A," 15,000 "B" Ordinary, and 7,000 Preference, and 10s. per share has been called on 2,288 Ordinary.

PACIFIC AND EUROPEAN TELEGRAPH CO. (LIMITED).—The annual return to Dec. 21 has been filed. The nominal capital is £100,000, in £10 shares, all of which have been taken up. £4 per share has been called.

PORTABLE ELECTRIC LAMP CO. (LIMITED).—The annual return to Jan. 2 states that the capital is £50,000, in £1 shares, of which 40,157 shares have been taken up; 40,000 shares have been issued as fully paid, and the remainder have been paid up.

POTTERIES ELECTRIC TRACTION CO. (LIMITED).—The statutory return to Nov. 17 gives the capital as £400,000, in £10 shares, of which seven have been taken up, but no calls have been made.

RYDE ELECTRIC LIGHT AND POWER CO. (LIMITED).—The annual return to Jan. 13 has been filed. Seven shares have been taken up out of the capital of £10,000, in £5 shares, but no calls have been made.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT CO. (LIMITED).—The annual return to Feb. 21 has been filed. The capital is £300,100, in 40,000 Ordinary and 20,000 Preference shares of £5 each, and 100 Founders' shares of £1 each. 31,980 Ordinary, 20,000 Preference and 100 Founders' shares have been taken up, and the full amount called.

SCARBOROUGH ELECTRIC SUPPLY CO. (LIMITED).—The annual return to March 2 has been filed. The nominal capital is £50,000, in £10 shares, of which 4,500 have been taken up; £9 per share has been called on 4,000, and £4 per share on 500.

TELEGRAPH IMPROVEMENT CO. (LIMITED).—The annual return to Jan. 12 has been filed. 15,006 shares have been taken up out of a capital of £100,000 in £1 shares, of which 15,000 have been issued as fully paid, while £6 has been paid on the others.

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The annual return to March 1 has been filed. The whole nominal capital of £399,500 in £5 shares has been taken up, and paid for in full.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (since Feb. 2, 1899). Price of silver 27 7/16d. per oz. (March 23). Consols (2¾ per cent.) 110⅝—110⅞ for money, 110¾—111 for account; 2½ per cent. 103⅜—103⅝ (March 23), Stock Exchange Settling Days: Consols, April 6; Stocks and Shares Continuation Days, March 27 and April 11; Ticket Days, March 28 and April 12; Pay Days, March 29 and April 13; Mining Share Carry over Days, March 25 and April 10.

ANGLO-AMERICAN TELEGRAPH CO. (LIMITED).—After placing £6,000 to credit of renewal fund, an interim dividend has been declared for the quarter ending 31st inst. of 15s. per cent. on the Ordinary stock, and £1. 10s. per cent. on the Preferred stock (less tax), payable on May 1.

BLACKHEATH AND GREENWICH DISTRICT ELECTRIC LIGHT CO. (LIMITED).—Capt. E. I. Bax, director of the South London Electric Supply Corporation, and manager of the Westminster Electric Supply Corporation, and Mr. Henry St. John Winkworth have joined the board of this company.

BRITISH CONTINENTAL ELECTRICITY CO. (LIMITED).—An interim dividend is declared on the Preference shares, at the rate of 5½ per cent. per annum for the half-year to Oct. 31, 1898.

BUENOS AYRES AND BELGRANO ELECTRIC TRAMWAYS CO. (LIMITED).—At the annual meeting on Wednesday, the chairman (Mr. John Morris) said that they had been operating under great disadvantages, inasmuch as the section of new line which was being worked electrically was only a fragmentary one until within a month or five weeks ago. For the first four weeks the traffics on the new section had been at the rate of something like £45,000 a year, and he saw no reason why that satisfactory return should not continue. They had always looked with satisfaction to the adoption of the electric system, but they had been somewhat startled by finding in the first four weeks of its introduction such a great jump as was shown in the traffic up to the point to which it had been carried. He would not indulge in any prophecy as to what the result would be as they extended towards Belgrano, and when the new system went to Belgrano itself, but the result so far had gone considerably ahead of their expectations. They were going on with the work on the new line up to Belgrano, and hoped to get it finished in a few weeks. Their intention was to go on applying electricity, from Belgrano right up to Centro America; there they would stop for a time until they could get further facilities for proceeding into the centre of the city. They already possessed the right to go there.

COMMERCIAL CABLE COMPANY.—The accounts for 1898 show that, after setting aside $100,000 as reserve for insurance of stations, apparatus, and repair steamer, and $350,000 to reserve, there was a balance profit for the year of $1,908,758, inclusive of $477,019 brought forward. Interest on the Four per cent. Bonds and Debenture stock absorbed $704,296, and the dividends declared during the year on the share capital (8 per cent.) $800,000, leaving $404,462 to be carried forward.

DAVIS AND TIMMINS (LIMITED).—This old-established firm of manufacturers of screws and terminals, engineers and metal merchants, has joined the list of joint-stock undertakings. The capital of the Company is £110,000 in 60,000 6 per cent. Cumulative Preference and 50,000 Ordinary shares of £1 each. The whole of this capital has been offered for subscription at par this week, and the applications closed yesterday (Thursday). Sir Henry C. Mance is chairman of the Company. The original business was established in 1676, in Charles-street, Hatton Garden, London, where the business was conducted until 1892, when factory premises were taken at King's Cross. The purchase price for the business is £87,000—£40,000 in cash and £47,000 either wholly or partly in cash or Ordinary shares, at the option of the directors, two of whom, Mr. Emile Davis and Mr. A. Le Neve Foster, are the vendors. The purchase price, from the somewhat meagre particulars given on the prospectus, seems a heavy one, as the average annual profits for the three years and 5 months from July 31, 1895, to Dec. 31, 1898, are certified at only £9,523, "without charging interest, directors' fees and management remuneration." The Company's business is, however, a progressive one, and in view of the great extension of the electrical industries and the large number of leading firms on the Company's books as customers, the Preference shares should be a reasonably safe investment.

EASTBOURNE ELECTRIC LIGHT CO. (LIMITED).—The directors' report for the year 1898 states that the gross profit, after paying working expenses, amounted to £4,574. 5s. 6d., against £3,619. 7s. 11d. in 1897. After allowing for debenture and preference interest, adding £400 to depreciation and paying an interim dividend for the half-year ended 30th June last, there remains £3,069. 13s. 10d., and the directors propose a dividend of 20 per cent. for the half-year (making 12½ per cent. for the year), free of tax, on the Ordinary share capital, leaving £1,120 to be carried over. It is not proposed to place any part of the surplus to reserve, but, on account of the exceptional circumstances in which the Company is placed, to keep it as a floating balance for any purposes required. Depreciation now stands at £3,391. 5s. 3d., while reserve remains at £3,250. The equivalent of 8 c.p. lamps in circuit was 23,028 at the close of 1898, against 19,288 in 1897. The report refers to the negotiations with the Corporation for the sale of the Company's undertaking, and to the offer of the former to give £20 for every £10 share. On examination it was found that, owing to the deductions claimed by the Council, the price named would provide only about £18 per share. The shareholders, therefore, unanimously rejected the offer. They consented, however, to name two shareholders to meet two members of the Council's committee to discuss the subject and to arrange terms if possible. As a result of the meeting the Council had withdrawn their demand for the deductions previously claimed, and had amended their former offer, so that the price should really provide twice the amount of the share capital subscribed and paid-up as a net sum to the shareholders without deduction. The whole subject is to be fully discussed at the forthcoming meeting.

EVERED AND CO. (LIMITED).—The directors of this Company, after providing for debenture interest amounting to £2,416, show a net profit of £25,698 for 1898, making with £6,361 brought forward £32,060.

EXPLORATION CO. (LIMITED.)—At the annual meeting on Wednesday, the Chairman said that there had been no alteration in their holding in the shares of the Central London Railway, the opening of which had been delayed owing to unforeseen difficulties. They were satisfied that when the line was opened it would meet a real want, and benefit the shareholders in proportion to its utility. Their holding in the Electric Traction Co. had been slightly increased. The position of the Compagnie Générale de Traction, the Ordinary and Founders' shares of which were largely held by them, had still further improved since the issue of the report, inasmuch as the concessions for electric tramway lines "de Pénétration" for Paris, asked for by the Compagnie, and approved of by the Conseil Général de la Seine, had received the sanction of the Conseil d'Etat, and it was expected that the official decree enabling work to commence would issue immediately. Through the enterprise of the Compagnie they were confident that Paris and its suburbs would at no distant date be covered with a network of electric tramways of over 200 kilometres of new lines. Such lines as were of importance to the exhibition of 1900 would be in working order at the time of opening.

Digitized by Google

GUILDFORD ELECTRICITY SUPPLY CO. (LIMITED).—The directors' report for the year 1898 states, that the balance profit on revenue account, after allowing £150 for depreciation, amounts to £149. 2s. 8d. The directors have also written off £77. 14s. 6d. for preliminary expenses. Since the last meeting, mains have been laid in several additional thoroughfares, and this extension has necessitated further expenditure in machinery and plant. There are now 79 customers, against 52 in March last year. During the year the price of current for lighting has been reduced from 8d. per unit (with varying discounts) to 6d. net. It will be necessary to expend further sums on mains, machinery and plant, and further capital is required. The directors are applying for an extension of their area of supply, and hope to obtain an order during the present session, adding to the company's present area the rural parishes adjoining the borough of Guildford within a radius of three or four miles.

HAMPSTEAD ELECTRIC SUPPLY CO. (LIMITED).—The *Financial Times* again calls attention to offers being made by a firm of outside brokers to unload shares in the above company, and warning its readers against having anything to do with the said shares.

PONTYPOOL ELECTRIC LIGHT AND POWER CO. (LIMITED).—The annual meeting was recently held at Pontypool. The directors' report stated that during the past year the further sum of £518. 6s. 10d. was expended in "free" wiring, and the additional customers brought in had put the company on a profit-earning basis. The directors, however, notified that they will discontinue the free-wiring system at the end of 1898, in order that they might consider their position. During the year, the station building had been extended, and a new boiler and steam dynamo had been erected, approximately doubling the capacity of the station. Certain extensions of the mains were also carried out, and in order to meet the capital expenditure entailed by these extensions, the directors made a fresh issue of £5,000 4 per cent. Debentures, out of which the previous issues (amounting to £2,000) were paid. The running of the station for the year ended December 31st (after carrying £100 to renewal) resulted in a net profit, which, with the balance from last year, amounted to £475. 5s. 2d.; and the directors recommended that £50 be carried to reserve, £150 to an account to be formed for redemption of Debentures, a dividend of 5 per cent. be paid upon the paid-up capital, and the balance (£13. 4s. 2d.) be carried forward. The report and accounts were adopted.

ROBEY AND CO. (LIMITED).—After putting £10,000 to reserve and carrying £352 forward, the Directors have declared a dividend of 10s. per share for the year 1898. It has been decided to pay off during 1899 the whole of the second issue of debentures, amounting to £46,305.

ROYAL ELECTRIC COMPANY OF MONTREAL.—Particulars are given in an advertisement elsewhere of the numbers of 77 4½ per cent. debentures, amounting to £7,700 which have been drawn for payment at £105 by the Bank of Montreal, 22, Abchurch-lane, London, E.C., on April 1. The coupons, due April 1, on the balance of these debentures, will be paid by the Bank of Montreal.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed Tuesday, 28th inst., a special settling day in the further issue of 2,500 £10 fully paid Ordinary shares (nos. 12,501 to 15,000) of *W. T. Henley's Telegraph Works Co. (Ltd.)* The shares, as well as the further issue of 40,000 4½ per cent. debenture stock of the *Chelsea Electricity Supply Co. (Ltd.)*, have been ordered to be quoted in the official list. Application has also been made to appoint a special settling day in and to grant a quotation to 37,500 ordinary £10 shares of the *City and South London Railway Co.*, and to appoint a special settling day in 233,334 5 per cent. cumulative £1 preference shares of *Doulton and Co. (Ltd.)*

UNION ELEKTRICITATS GESELLSCHAFT.—A dividend of 12 per cent. for the year 1898 has been declared.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated amount of the traffic receipts of this company for the half-month ended March 15 is £2,667, against £1,890 in the corresponding period of 1898.

NOTES.

SMOKE has once again been a source of anxiety to one of the metropolitan electric supply companies, the Charing Cross and Strand Company having, on Monday last, been summoned before Sir JAMES VAUGHAN for disobeying an order to prevent black smoke from being emitted from their chimney so as to cause a nuisance. It appears that, notwithstanding the use of fuel consisting of a mixture of coke with the best Welsh coal, the fumes emitted from the chimney were not above suspicion. On the one hand, residents in the neighbourhood are said to complain that they dare not open their windows; on the other hand, the Company protested that they have done the best they could to prevent smoke, and, consequently, claimed exemption from further proceedings. Sir JAMES VAUGHAN adjourned the summons *sine die*, in order that an expert, to be nominated by the President of the Institution of Civil Engineers, might examine the boiler plant, &c. In thus acting he has adopted a course which might well be followed whenever similar difficulties arise in future.

WITH the assiduity of a SHERLOCK HOLMES, Mr. A. P. TROTTER has been following up a series of clues as to electrical earth currents in the vicinity of Cape Town. In his garden at Wynberg, he arranged an automatic recording current meter, the records of which, taken over a lengthy period, revealed three distinct sources of electric current in the ground. The chief effect was undoubtedly due to the tramways; a second appeared to be traceable to sun-spot phenomena; while the third, absent on moonlight nights and always ceasing with clockwork regularity at midnight, was clearly caused by leakage from the public lighting mains. At Cape Town, as in many other places, the street lamps are not switched on when the moon shines nearly full.

OTHER matters are also dealt with in the report wherein Mr. TROTTER embodies these observations. The wanderings of the earth currents have been mapped out, and their tendency to do electrolytic and other mischief scrutinised Currents have been traced some distance out to sea, while at one part of the beach it is possible to light a glow lamp from electrodes stuck in the sand. Another feature of electric traction, as practised at Cape Town, elicits from Mr. TROTTER a sly dig at the rough-and-ready style of American practice, as shown by the noise which the car gears persistently make. In a country, he says, where unusual industrial activity is quaintly described as "making things hum" it is quite possible that a noise of this kind, so far from being a nuisance, may be regarded as an indication of progressive enterprise. Our readers will probably, however, sympathise with Mr. TROTTER'S English taste for silent gears, and will prefer that our home tramways should be equipped with home-made gears having nothing of the American propensity to "hum."

A BRISTOL firm of wiring contractors has, at the request of Mr. FARADAY PROCTOR, the Corporation engineer, sent us some photographs of joints and wires taken out of a house wired, they believe, by an amateur some two years ago. The wires were, we are told, run through holes in the walls and under the floors, without pipes or casing, and the joints, with two poor exceptions, were unsoldered. Two of the unsoldered joints were insulated with a piece of old lace curtain. In one place a mouse had eaten away the insulation of the wires and caused a short circuit, the electrocuted mouse having been found at the spot. Such examples of wiring as this point two ways: first, to the false economy in cheap and nasty wiring, as the installation has had to be remade in two years; and secondly, to the needlessness of strict fire office rules, for in spite of unsoldered joints, in some cases blackened by heating and lace insulation, no fire occurred during the two years the work held together.

THERE has been, during the last few months, an epidemic of international technical dictionaries, but, notwithstanding this, we appear to be as far as ever from having a thoroughly useful and up-to-date reference book of this kind. A

Digitized by Google

technical dictionary is wanting that does not confine itself merely to one branch of technics, but which covers the whole ground, supplying completely those words and phrases which are of necessity omitted from general dictionaries. The various applications of science and engineering are so intimately connected that they permit of no sharp boundary line, and a list of scientific and technical terms used in one branch alone is not found sufficient by the majority of readers of foreign technical literature. Although such a book is urgently needed, it is evident, from commercial considerations, that its realisation is hardly to be expected at present. A really good work of the kind would entail not only the services of an able cosmopolitan editor prepared to devote years to its compilation, but would also require a large staff of collaborators representing almost the product of the number of languages with the number of technical subjects dealt with. Even if one man could be found who would be sufficiently self-sacrificing to devote himself to the task of editor with but a faint prospect of pecuniary recompense, it would be extremely difficult to obtain this army of disinterested helpers. Or, if the payment were to be adequate, what publisher would be prepared to guarantee this and take the risks of publication?

The *rôle* of publisher of such an international technical dictionary appears to us, however, to be one eminently suited to a representative scientific or engineering society or to several of such societies in conjunction. Recently one such body has resolved to prepare a general international scientific index, and others have been devoting a great deal of attention to the question of publishing abstracts of articles on scientific and engineering subjects which have appeared in foreign papers and periodicals. However excellent such productions may be, they can contain in most cases little more than bare summaries of articles, and it must always be left to independent technical journals to publish translations or fuller abstracts, and to guide their readers by comment and criticism. Exigencies of space naturally compel these journals to omit much that is not unimportant and to deal only with those matters likely to interest a fair proportion of their readers. Those, therefore, wishing to study in detail articles of which full abstracts have not been published, must have recourse to the originals, and, even with a fair knowledge of foreign languages, this is often a hard task, owing to the multitude of words not to be found in the ordinary dictionaries. The whole question is worthy of consideration by the Royal Society and the Institution of Civil Engineers and allied technical societies.

Our contemporary *l'Industrie Electrique* publishes in its issue of March 10th its annual table of electric traction statistics for all European countries. Germany still leads the way in the number and length of lines in power-house capacity, and in the number of cars running, France coming next with 56 lines of an aggregate length of 303 miles, a power-house capacity of 18,718 kilowatts, and 759 motor cars. Great Britain and Ireland, of course, come next, but we note that some lines have been omitted, for the total number should be 84 instead of 81, and the total mileage 240 instead of 145. We notice also that the Bessbrook-Newry line is entered both in England and Ireland, and that in the former country its maximum gradient is 2 per cent., and in the latter 1 per cent. On the other hand, the Giant's Causeway railway appears only in England. The *French* Thomson-Houston Company are said to have built the Dublin tramways, and Cork is among the towns omitted. Altogether Ireland is badly treated. We notice that the German lines have not been quite fully reported either, the totals being considerably less than those published by the *Elektrotechnische Zeitschrift* last January, and referred to in our issue of January 27. The number of electric tramways and railways in Switzerland has increased considerably since last year. There are now 32 lines, all worked on the overhead system, the aggregate length being 125 miles, the plant capacity 6,665 kilowatts, and the number of motor cars and locomotives 325. In France 42 out of the 56 lines are on the overhead system, two underground conduit, one central rail, six simple accumulator system, four "mixed" trolley and accumulators and one trolley and conduit.

Correspondence.—Pressure on our space compels us to hold over several letters until next week.

Cable Interruptions.	Date of Interruption.
Paramaribo—Cayenne	Feb. 10, 1899
Cayenne—Pinheiro	Mar. 10, 1899

Opening of Blackburn Tramways.—The Corporation electric tramways, described in our issue of the 24th inst., were formally opened on Wednesday last.

Royal Institution.—Among the lecture arrangements for after Easter are the two Tyndal lectures by Prof. Silvanus P. Thompson on "Electric Eddy Currents." The Friday evening meetings will be resumed on April 14th, when a discourse on "Earth Currents and Electric Traction" will be delivered by Prof. A. W. Rücker.

Uninsulated Middle Wire.—An electricity supply station has been built at Bonn (Germany), on the 2 × 220 volt three-wire system, with a bare middle wire. The station has only recently started a regular supply, and has at present a lamp-connection equivalent to 24,000 8 c.p. lamps. The plant includes two 250 H.P. steam dynamos and an accumulator battery, and a third steam-dynamo of 650 H.P. is on order.

Röntgen Ray Burns.—Interest has been aroused in medical circles in Paris, says the correspondent of the *Daily Chronicle*, by legal proceedings which are about to be taken owing to alleged dangerous burns caused by the examination of a woman's thigh under Röntgen rays. The burns are said to have developed symptoms of gangrene after three exposures to the rays. Damages to the amount of 5,000f. are claimed.

Papers on Electric Arcs.—Mrs. Ayrton's Paper on "The Hissing of the Electric Arc," read at the Institution of Electrical Engineers last week, together with the unread Paper on "Experiments on Alternate Current Arcs by Aid of Oscillographs," by W. Duddell and E. W. Marchant, which appears in Part 138 of the *Journal*, will conjointly form the subject of a discussion to take place at the next meeting of the Institution on April 13th.

Effect of the Copper "Boom" on the Price of Old Trolley Wire.—According to the *Electrical World* of New York, the Brooklyn Heights Railroad Co. is having an anomalous experience in replacing its worn out trolley wire. A company had executed a contract last year providing for the delivery throughout 1899 of new wire at prices in accordance with the then market value, and since then the price of copper has gone up so much, that the company is obtaining more for its old wire than it is paying for the new material.

The Use of Electricity on American Warships.—The authorities at Washington have decided that electricity shall

Digitized by Google

not be employed to operate the auxiliaries on the five new battleships now in course of construction. This seems the more remarkable as a short time ago the officers of the cruiser "Brooklyn," in a report sent in to the Navy Department, referred in the highest terms to the advantages of electricity over steam for operating the auxiliary machinery on men-of-war, referring particularly to the experience gained in the war with Spain.

Personal.—It is officially announced that the Postmaster-General has been pleased to appoint Mr. W. H. Preece, C.B., to be consulting engineer to the Post Office.

In the report in our last issue of the dinner to Mr. Charles Gerhardi, it should have been stated that he has been 46, and not 42, years in the telegraphic service, of which he is now the *doyen* in active work.

We are glad to learn that Sir Eyre Massey Shaw, K.C.B., chairman of the Metropolitan Electric Supply Co., is quite restored to health.

Accident Returns of an Electric Tramway System.—The following record of the disturbances to traffic on the Hamburg electric tramways during 1898 is of interest:—Caused by motor cars, 311; by derails and collisions, 127; by trailers, 14; by overhead wire, 7; and by an occurrence in the power station, 1. The figures are not large when it is considered that over 10 million car-miles were traversed during the year. Of the seven faults on the overhead wire, one affected the traffic for $3\frac{3}{4}$ hours, two for 30min. each, and the remaining four from 6min. to 10min.

First Wireless International Press Message.—The following is the first Press message transmitted by wireless telegraphy across the Channel. It was despatched on Tuesday last by a correspondent of *The Times*:—

Communication between England and the Continent was set up yesterday morning by the Marconi system of wireless telegraphy. The points between which the experiments are being conducted are South Foreland and Wimreux, a village on the French coast, two miles north of Boulogne, where a vertical standard wire, 150ft. high, has been set up. The distance is 32 miles. The experiments are being carried on in the Morse code. Signor Marconi is here conducting the trials, and is very well satisfied with the results obtained.

Thawing Water-Pipes by Electricity.—In the United States, where water-pipes freeze more often than in this country, it has been discovered that a good means of thawing them is to pass an electric current from one end to another of the frozen portion. This electric heating, if not carried too far, is found to break up the ice without damaging the pipe in any way. A disadvantage to the method was recently found in a town in Indiana, however, where the leakage current through the earth caused all the telephone indicators of subscribers in the district to drop, the telephone lines being on the earthed return system.

An Electric Crane for Kiao-Chow.—The *Elektrotechnischer Anzeiger* states that a 150-ton electric crane is shortly to be erected in Kiao-Chow harbour. It will be fitted with two winding gears of 75-ton capacity, which can be used singly or coupled, and a smaller winding gear of $2\frac{1}{2}$ tons capacity. It will be driven by two 100 H.P. motors, and the swinging extension of the gib will be capable of bearing 70 tons in its lower and 150 tons in its upper position. Two additional 100 H.P. motors are employed to actuate the gib extension, and a 20 H.P. motor to turn the crane. Needless to say, the order for the crane was placed with a German firm.

Cable Specifications.—Six of the leading cable manufacturers in Austria and Hungary have, at the suggestion of the Austrian Electrical Society, decided on certain standard sizes and denominations for various classes of insulated wire and cable used for electric light installations. They give notice that from July 1 next they will deliver according to these standards only. Fourteen conductor sections have been chosen, from 1 to 150 sq. mm., four different specifications for cotton and rubber-covered single wire and cable, three types of multiple wire and three varieties of lead covering and armouring.

Damages for Electrolysis.—The City of Chicago has sued the Chicago North Shore Street Railway Co. for $500 damages, which is claimed for injury done to the city water mains by electrolysis. The claim is based upon the assertion that a large portion of the return current from the company's trolley line passes through the water main, and at a point opposite the power house, where it leaves the main, very serious disintegration of the iron pipe has taken place. The *Railway and Engineering Review* (Chicago) states that this suit has been brought as a test case to determine whether a street railway is liable for damage of this kind.

An Electrically-Heated Surgical Operating Table.—Dr. H. Lewis Jones, of St. Bartholomew's Hospital, is now working out, in conjunction with Messrs. Arnold and Sons, the details of an electrically-heated operating table in which incandescent lamps supply the heat. The body of the table has the form of an air chamber of metal, which may be divided into separate sections for convenience. Six or eight 16 c.p. lamps enclosed in this chamber will rapidly raise an operating table to the required temperature, and half that number will then maintain the temperature at a proper level when the rest have been switched off. Wherever electric light circuits exist, this mode of warming an operating table, says Dr. Jones, would present decided advantages.

The Albert Medal.—The Council of the Society of Arts will proceed to consider the award of the Albert Medal for 1899 early in May next, and they invite members of the Society to forward to the Secretary, before April 8, the names of men of high distinction who they think are worthy of this honour. The medal was struck to reward "distinguished merit" in promoting arts, manufactures or commerce, and is bestowed annually. It was first awarded in 1864 to Sir Rowland Hill, and among other recipients are: H.I.M. Napoleon III., Michael Faraday, Sir W. F. Cooke, Prof. Charles Wheatstone, Sir Joseph Whitworth, Viscount F. de Lesseps, Sir Henry Bessemer, Sir George B. Airy, Lord Armstrong, Lord Kelvin, James Prescott Joule, Thomas Alva Edison, Prof. David E. Hughes and Prof. R. W. Bunsen. The last-mentioned received the medal in 1898.

A 95-Volt Arc.—Mr. Alton D. Adams, in the *Electrical Engineer* of New York, describes a method he employs to obtain a steady arc with so much greater length than is customary, that it takes a pressure of 95 volts and yet burns steadily. He shunts an induction coil to the series coils of the usual series-coil arc lamp, and does away with the usual dead resistance. Some of these lamps are in use in Boston, and are said to burn well. The following tests show the gain in efficiency which is claimed:—

	Long arc.		Short arc.
Volts at main	110·0	...	110·0
Volts at arc	95·3	...	78·1
Amperes	4·19	...	4·12
Watts to lamp	461·0	...	452·0
Watts to arc	398·0	...	322·0
Mean spherical c.p.	128·0	...	91·3
Watts per spherical c.p, lamp	3·59	...	4·96
Watts per spherical c.p. arc	3·11	...	3·50
Gain in efficiency in lamp	27 per cent.		
Gain in efficiency in arc	11 per cent.		

One watt taken by lamp will give 35 per cent. more light. Clear inner and opal outer used.

The Electric Railway and Tramway Carriage Works.—The new works of the Electric Railway and Tramway Carriage Works (Limited) were opened at Preston on the 23rd inst. These works have been built with a view to supply the British and foreign markets with electrically equipped tramways and rolling stock, and we understand that in their present state of development, they are capable of turning out as many as three cars a day. Two hundred men are at present employed, but it is expected that this number will shortly be increased to 600 or 700. The buildings include a number of spacious shops for car building and erecting on the trucks, &c., together with an engine house and boiler house for generating electric power. In the boiler house there are erected two Galloway boilers rated at 225 H.P., while in the adjoining machinery house there is a horizontal compound steam engine direct-coupled to a Mather and Platt multi-polar dynamo. This generating set is rated at 325 H.P., running at 150 revolutions under a steam pressure of 120lbs. A storage battery set has been erected, consisting of 170 chloride cells, with which it is intended to light the buildings during the night or to supply,

Digitized by Google

occasionally, power during the day. The whole of the machine tools throughout the works are operated by electric motors, the larger tools being driven by separate motors and the smaller ones grouped on line shafts. There are now some 25 electric motors of from 10 H.P. to 45 H.P. distributed throughout the works.

Temperature Coefficients of Copper.—The majority of wire and cable manufacturers have been content to use Matthiessens' temperature correction when measuring the resistance of copper wire, and in submarine cable work the same coefficients have also always been considered sufficiently reliable, although they were obtained before copper of such a degree of purity as at present was on the market. Matthiessen found that the temperature coefficient increased with the conductivity, and he gave a law by which the temperature coefficient of the commercial metal could be calculated from that of the pure metal when the conductivity of the former was known. Messrs. Clark, Ford and Taylor have found that, although until the last few years the mean temperature of a laid cable could be calculated from a "compound interest" formula, so as to agree actually with thermometer observations, in a recent case, where the thermometric survey of the cable route had been carried out with unusual completeness, a large discrepancy was apparent. They have, therefore, carried out a series of tests on six samples of copper wire supplied to the Telegraph Construction and Maintenance Co. by five of the largest wire manufacturers. The tests were carried out by the potentiometer method, using a standard resistance of manganin wire, the potentiometer being divided into 20,000 equal parts. The thermometers had been verified at Kew, and their zero points recently checked; they were divided to 0·1 and 0·2°C. It was found that the temperature coefficients of the wires were almost identical, but that they differed to some extent from Matthiessen's standard, the formula obtained being $R_t/R_{32} = 1 + 0{\cdot}0023708\ (t-32) + 0{\cdot}0000003458\ (t-32)^2$, for the Fahrenheit scale. This formula, when employed for calculating from the conductor resistance the mean temperature of the cable referred to above, gave results agreeing to within 0·3°F. with the thermometric observations, while with Matthiessen's coefficient the difference amounted to 3·3°F. Messrs. Clark, Ford and Taylor have published a neatly-arranged, leather-bound booklet recording their observations, giving a curve of their results alongside one drawn from Matthiessen's formula, and including three tables. The first of these gives resistances at different temperatures when R = 1 at 32°F., the second when R = 1 at 75°F., and the third contains logarithmic coefficients for calculating the resistance at 75°F. from observed resistances.

New French Wiring Rules.—The Chambre Syndicale des Industries Electriques has issued a revised code of wiring rules, the previous set having remained unaltered since 1892. On the whole they are much less strict than the rules enforced in England. The following are some of the main points of difference:—Cables and wires are to have a conductivity of at least 90 per cent.; 100 per cent. conductivity being defined as that corresponding to a resistivity of 1·80 microhm centimetre at 20°C. The maximum drop of voltage to the farthest lamp is fixed at 3 per cent., but the section of wire is to be such that when carrying double its normal current, the rise in temperature is less than 40°C. For this the following current densities are given: 3 amperes per sq. mm. for sections of from 1 to 5 sq. mm., 2 amperes per sq. mm. for sections of from 5 to 50 sq. mm., and 1 ampere per sq. mm. for larger cables. The smallest conductor which may be employed is a single wire of 0·9 millimetre diameter. Bare wires are forbidden "*en principe*," but allowed in special cases. Practically no specification for the insulation of conductors is given. In distinction to the other easy regulations it is laid down that metal covers are not allowed on switches or fuse-holders. Fuses are to be marked with the number of amperes of the circuit which they protect, and are to fuse at three times that current. The rule as to the undesirability of an intermediate position between "on" and "off" in switches, which is generally adopted in this country, applies only to "when the break may cause an electric arc, for instance above 2 amperes at 100 volts." Fuses are to be placed on every circuit and at every branch down to 5 amperes. Fittings, such as electroliers, must be insulated at their point of attachment. Combination gas and electric fittings are allowed, but they must be insulated from the gas pipes by half a megohm. The lamp holders must be insulated from the fitting, and the wires on them must be efficiently insulated and protected, and be of such a nature that the heat of the gas does not harm them. The insulation resistance, either to earth or from wire to wire expressed in ohms, must not be numerically less than five times the square of that number of volts working pressure for each section of the conductor which can be separated from the remainder by turning a switch or taking out a fuse. While considerably increasing the labour of testing, this last rule will not necessarily bring the insulation resistance of the whole installation up to a very high standard.

150-Ton American Electric Crane.—The Newport News Shipbuilding and Dry Dock, in Virginia, although well provided with appliances for handling material, was found to be in need of apparatus more powerful and more convenient than the 100-ton sheer legs which had been used for handling the heavier weights. Careful consideration led to the adoption of a 150-ton revolving derrick, electrically operated and controlled, mounted on a steel tower supported in turn by pile foundations. The derrick jib is capable of having its outer end raised or lowered, thus giving to the hoisting blocks, which depend vertically from this end, a movement not only of rotation about the centre of the derrick, but also of translation in or out from this centre. With the outer end of the jib in its lowest position the hoisting blocks will, on rotation of the derrick, describe the circumference of a circle 207ft. diameter; with the jib in its highest position these blocks, on rotation, describe the circumference of another concentric circle 88ft. in diameter. Weights up to 70 tons may be handled throughout the entire range. The derrick is revolved by duplicate sets of machinery, each consisting of one G. E. 800 railway motor, capable of developing 20 H.P., and driving, by means of a double threaded worm and wheel, a pinion which, engaging a horizontal circular rack on the outside of the tower, gives the required rotation. The motors are series wound and controlled from a series parallel controller, giving high efficiency under starting conditions as well as at normal speed. The turning motion is very smooth and perfectly noiseless, and requires very little power. The racking movement of the jib is effected as follows:—At the inner and upper apex of the jib is a 10in. steel pin carrying 22 cast-steel sheaves, each sheave of 5ft. pitch diameter. At the upper apex of the housing is another 10in. steel pin carrying 24 similar sheaves. Leading over these two sets of sheaves and sustaining the weight of the jib and load, are two 1¼in steel wire ropes, each rope being wound on alternate sheaves, and each end of each rope brought down to separate drums, located below in the housing, this arrangement ensuring freedom from side twisting on the sheaves and also requiring each rope to take its share of the weight. The four drums, on which these ropes are wound, are arranged in pairs, each one of a pair taking opposite ends of the same rope and each pair driven by a G. E. 2,000 series motor of 100 H.P., the power from the motor being transmitted to each drum through a separate train of gears. The drums are of cast-iron, 5ft. pitch diameter, carried by 7in. steel shafts. The main hoists are each of 12 parts, 1¼in. steel wire rope, leading over six sheaves, 5ft. pitch diameter, carried on a 10in. steel pin at the outer end of the jib. The lead from these sheaves to the operating drum is carried down the jib on wooden roller runners. These drums, one for each hoist, are of cast-iron, 8½ft. pitch diameter, carried on 7in. steel shafts, and each driven through a train of gears, by a 100 H.P. G. E. motor, series wound. These hoists may be coupled together and operated as one hoist of 150 tons capacity. The 20-ton whip is of three parts, 1¼in. steel wire rope, carrying a single block and leading over two sheaves, carried, as are those for the main hoist, at the outer end of jib. The lead from these sheaves passes down the jib, over a single guide sheave, to a cast-iron drum, 8½ft. pitch diameter, driven through a train of gears by a 100 H.P. series wound motor.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

"Continuous" Discharges.—Using the most sensitive wave detectors at his command, Hertz found that when batteries of sufficiently small resistance were used, their discharge through a vacuum tube was apparently continuous. As in the case of spectrum analysis or of astronomical nebulæ, this may mean that there is real continuity, or that our instruments are not sufficiently sensitive to discover any discontinuity. M. Cantor has, therefore, tested the matter with the aid of that supremely sensitive modern device, the coherer. He placed a battery of 1,000 accumulators in the cellar, and connected it by thick copper wires with the laboratory on the second floor. On joining the cathode of the vacuum tube with the leaves of an electroscope, and through a liquid resistance with its metallic case, the form of discharge described by Hertz was found to be apparently continuous, since the electroscope showed no divergence. But, under the same circumstances, a coherer filled with small iron screws showed the presence of waves distinctly. A number of controlling experiments, undertaken to eliminate sources of error, led to the same result. It remains now to find whether any portion of the discharge is continuous, or whether there is altogether no such thing as a continuous discharge in vacuum tubes.

[Cantor, *Wied. Ann.*, No. 2, 1899.]

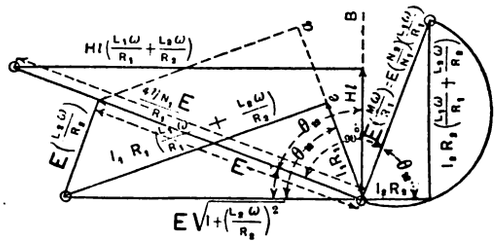
Propagation of Waves Along Wires.—The problem of the propagation of Hertzian waves along a wire is of such fundamental importance that an exact mathematical treatment on the basis of Maxwell's theory would be very desirable. The chief difficulty encountered lies in the exact discussion of a transcendental equation whose root gives the rate of propagation and the damping in the interior of the wire. Hitherto the calculations attempted have been of an unpractical nature, on account of the assumption of an infinite thinness of the wire (Hertz); or another assumption, that the lines of force are normal to the surface of the wire (Poincaré), which they could only be if the propagation took place with the velocity of light. A. Sommerfeld discards these assumptions, and proceeds further on the lines already indicated by J. J. Thomson, treating the case of a single straight infinite wire. He shows that when the frequency is high and the wire thick, the propagation is very nearly at the rate of the velocity of light; but when that is not the case, as, for instance, when there is a platinum wire of 0·004mm. diameter, and the frequency is only 3×10^8 per second, the rate is only three-quarters of that of light. As far as the wire is concerned, all the occurrences take place in a layer not more than 0·01mm. thick.

[Sommerfeld, *Wied. Ann.*, No. 2, 1899.]

Nature of Cathode, Lenard and Röntgen Rays.—In a synthesis of existing theories, W. Sutherland attempts to frame a more or less complete theory of the relations between cathode and Lenard rays on the one hand and Röntgen rays on the other. Briefly, he regards the cathode and Lenard rays as streams, not of ions, but of free negative electrons. The Röntgen rays, on the other hand, are caused by the internal vibrations of the free electrons. To the electrons he assigns inertia and size, and, therefore, also shape; but a general conception of shape involves also the notion of deformability, which, therefore, we must consider as a possible property of the electron. The electron is, therefore, to be supposed capable of emitting vibrations due to the relative motion of its parts. These vibrations are transmitted by the luminiferous ether, but they and light itself need have nothing else in common. The author identifies Röntgen rays with these vibrations. Appreciable Röntgen radiation is only to be looked for when free electrons are thrown into vigorous internal vibrations, as happens when cathode electrons impinge upon the walls of the vacuum tube. Swinton's observation that two colliding cathode streams do not give rise to Röntgen rays is explained by the smallness of the electrons and their distance apart.

[Sutherland, *Phil. Mag.*, March, 1899.]

New Transformer Diagram.—F. G. Baum expresses the instantaneous values of the three varying quantities—primary current, secondary current, and magnetic flux—with their angular relations, in terms of the inductance and resistance of the two coils and the impressed E.M.F. The resulting diagram is simple, and applies to every case, and the method of obtaining it is straightforward. The algebraic process upon which the diagram is based is such that it is no more difficult to solve analytically any transformer problem than it is to solve any problem in the simple alternating-current series circuit, the solution of any transformer problem being, in fact, reduced to the latter. In the annexed diagram, which applies to the case of a non-inductive secondary and no



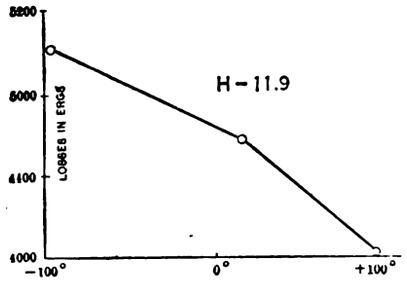
hysteresis, the letters H_1, R_1, R_2, L_1, L_2, ω have the usual signification; l is the length of the magnetic circuit, N_1 N_2 are the turns on the primary and secondary respectively. E is the maximum impressed E.M.F. on the primary. The apparent E.M.F. on the primary is

$$E\sqrt{1+\left(\frac{L_2\omega}{R_2}\right)^2},$$

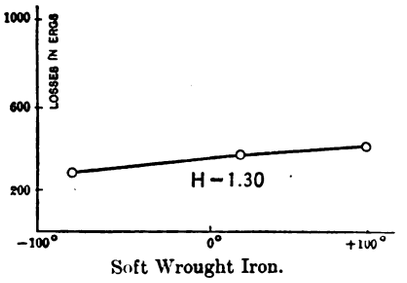
the phase being in advance of the real E.M.F. by an angle whose tangent is $\frac{L_2\omega}{R_2}$.

[Baum, *Phys. Rev.*, Feb., 1899.]

Hysteresis at Low Temperatures.—A. H. Thiessen has compared the hysteresis of iron and steel at ordinary temperatures with their hysteresis at the temperature of solid carbon dioxide, and has obtained results different from those of Fleming and Dewar, who found no difference in the hysteresis loss per cycle at ordinary temperatures and the temperature of liquid air. As the accompanying diagrams show, the loss changes



Soft Wrought Iron.



Soft Wrought Iron.

considerably with the temperature, being greater in the cold when the field is strong, and somewhat less when it is weak. The apparent discrepancy may either be due to the fact that there is a maximum or minimum somewhere between the temperature of solid carbonic acid (−80°C) and liquid air (−185°C), or, as the author prefers to suppose, by the fact that Fleming and Dewar's method is subject to errors due to Foucault currents or time lag. The author used the ballistic method.

[Thiessen, *Phys. Rev.*, February, 1899.]

Resistance as Influenced by the Surrounding Dielectric.—Since it is now almost universally believed that the energy of a current is propagated, not through the wire, but through the surrounding dielectric, it is natural to suppose that the nature of the dielectric has some influence upon the rate at which this energy is dissipated, in other words, upon the resistance of the wire. Such an influence was suspected in 1892 by Sanford, and announced as necessitating a modification of Ohm's law. J. F. Merrill has since repeated Sanford's experiments with copper wire, using elaborate precautions against changes of temperature and other sources of error. He claims to have proved that if kerosene, absolute alcohol and its vapour, and the vapours of ether, gasoline, benzine, and chloroform have any modifying influence upon the wire which they surround, the resistance of the latter does not change in any case more than by about 0·01 per cent., which is within the limits of experimental error.

[MERRILL, *Phys. Rev.*, February, 1899.]

Canal Rays.—It is quite possible that cathode rays will soon cease to be the chief object of interest in vacuum phenomena, and that their place will be taken by the positive rays, anode rays, or canal rays, as they are variously termed. For there can be little doubt but that these rays consist of projected metallic particles or ions, and it is just these metallic ions which play the most important part in the vast majority of electrical phenomena. We have recently seen Broca prove the disintegration of an anode emitting positive rays. Now we have A. Wehnelt investigating how a mica cross introduced into the dark cathode space casts a shadow, not upon the anode, but upon the cathode itself. This fact, first observed by Schuster, is supplemented by the important observation that the size of the shadow is independent of the distance between cross and cathode, provided the cross always remains within the dark cathode space. Within the region covered by the shadow, no canal rays appear on the other side of the perforated cathode, which confirms the view that canal rays are simple anode rays which are not intercepted by the cathode. The author further makes it extremely probable that no cathode rays are given off except where anode rays impinge, thus making them the primary phenomenon. He obtains a permanent silhouette of the cross by oxidation of the copper cathode where the anode rays impinge upon it.

MAGNETIC LEAKAGE IN THE ALTERNATING CURRENT TRANSFORMER.

BY ALEXANDER RUSSELL, M.A.

(Continued from page 604.)

Calculation of ϕ_1, A_1, W_1, V_2. W_2 *and* η *for given Secondary Currents from Initial Data.*—In calculating the following table, the following data only are assumed:—1. $W_0 = 34{\cdot}5$. 2. $A_0 = 1{\cdot}462$. 3. $Q = 0{\cdot}40$. 4. $E_2 = 117{\cdot}5$. 5. $\alpha = 6{\cdot}5$ deg. when the secondary current is three amperes.

No. of experiment.	A_2	ϕ_1	A_1	W_1	V_2	W_2	η
1	0	66·9	1·462	34·5	117·5	0	0
2	0·302	49·2	1·786	70·0	117·0	35·3	0·505
3	0·511	40·9	2·084	94·5	116·7	59·6	0·631
4	1·004	29·2	2·912	163·0	115·9	116·0	0·763
5	1·427	24·0	3·683	202·0	115·3	165·0	0·815
6	1·817	21·1	4·428	248·0	114·4	208·0	0·838
7	2·344	18·7	5·439	309·0	113·5	266·0	0·861
8	2·972	17·5	6·673	382·0	112·3	334·0	0·874
9	3·365	17·0	7·446	427·0	111·5	375·0	0·878
10	3·992	16·9	8·714	500·0	110·1	440·0	0·880
11	4·512	17·2	9·946	570·0	108·9	491·0	0·862

In this table the column headed A_2 is taken from the preceding table. The column headed ϕ_1 is calculated by the formula

$$\tan \phi_1 = \frac{A_0 \sin \phi_0 + n A_2 \sin \alpha}{A_0 \cos \phi_0 + n A_2 \cos \alpha}.$$

It is interesting to note that ϕ_1 attains its minimum value before full load and is beginning to increase.

The column headed A_1 is calculated by the formula

$$A_1 = A_0 \frac{\sin (\phi_0 - \alpha)}{\sin (\phi_1 - \alpha)} \quad . \quad . \quad . \quad . \quad . \quad (20)$$

W_1 is then got by evaluating $V_1 A_1 \cos \phi_1$.

V_2 is calculated by

$$V_2 = 117{\cdot}5 \cos \alpha - 1{\cdot}5 A_2.$$

W_2 equals $V_2 A_2$, and the last column is simply

$$\eta = \frac{W_2}{W_1}.$$

This method of calculating the efficiency is not to be commended as it is affected by errors in calculating A_1, ϕ_1 and V_2. A much simpler and more accurate method is given below.

Experiment with Wechsler Machine (rounded curves).—Frequency 41. Induction density in iron core about 11,700. The same notation and formulæ used as above.

Direct Calculation of the Efficiency of the Transformer (1) *when used with the Ganz Machine and* (2) *when used with the Wechsler machine.*—(1) The only data assumed are that $Q = 0{\cdot}40$ and $W_0 = 34{\cdot}5$.

$$\eta = \left(1 - \frac{34{\cdot}5}{W_1}\right)\left(1 - \frac{0{\cdot}4 W_1}{3600}\right).$$

The above formula is equivalent to the graphical construction given in *The Electrician* for March 25, 1898.

No. of experiment	2	3	4	5	6	7	8	9	10	11
Obs. efficiency ...	0·494	0·607	0·747	0·800	0·822	0·841	0·856	0·864	0·864	0·863
Calc. efficiency ...	0·514	0·645	0·767	0·812	0·839	0·860	0·872	0·876	0·880	0·880

These calculated results do not agree very closely with the observed results. They agree, however, with the efficiencies calculated from the observed readings in the secondary circuit (see below). In such a small transformer, if we want a three-figure accuracy, we cannot neglect the last term in formula (12). In this case it equals +0·002 at full load, hence this ought to be added to the last eight of the calculated efficiencies above.

In the above calculations no attempt has been made to take into account the differences in the core loss and the copper resistances at no load and full load. In practice it is not difficult to take these into account, and so determine the efficiency with great accuracy. In the above transformer the core loss is considerably less at full load than at no load. The back E.M.F. in the primary circuit at full load (B C in Fig. 1) is $V_1 - RA_1 \cos\phi_1$ nearly, and this equals 60 – 2, *i.e.*, 58 volts. Hence the induction density at full load is 3·3 per cent. less than at no load, and, therefore, the hysteresis loss is 5·3 per cent. less. The eddy current loss will be 6·6 per cent. less due to the diminished value of the effective E.M.F. caused by the driving flux besides a further diminution due to the increase in the specific resistance of the iron with rise of temperature. How the copper resistances (of any particular transformer) vary with the load is a matter to be determined by experiment. Dr. Roessler has given us the limits between which these resistances vary in the transformer he experimented on, and the above figures show that no great error is introduced in the calculations in which they occur by assuming them to be constant.

Mathematical Example.—The height of the centre of gravity of the E.M.F. wave produced by an alternator A is twice as great as that produced by an alternator B, the effective value of the volts in each case being 2,500. A 10-kilowatt transformer tested with the former alternator gave a core loss of 100 watts on open circuit, and a tenth of this loss was due to eddy currents. If Q equals 10 ohms find the efficiency of this transformer at one-twentieth, one-tenth, one-half and at full load : (1) when tested with A ; (2) when tested with B.

Since the height of the centre of gravity of the wave produced by B is only one-half the height of that of A, the maximum induction density in the core is twice as great when tested on B. Hence, by Steinmetz's law, the core loss when tested on B will be

$$2^{1{\cdot}6}(100 - 10) + 10 \; ; \; i.e., \; 282{\cdot}8 \text{ watts.}$$

Using the formulæ

$$\eta_A = \left(1 - \frac{100}{W_1}\right)\left(1 - \frac{10W_1}{2{,}500^2}\right)$$

and

$$\eta_B = \left(1 - \frac{283}{W_1}\right)\left(1 - \frac{10W_1}{2{,}500^2}\right)$$

we get

Load.	$\frac{1}{20}$th.	$\frac{1}{10}$th.	$\frac{1}{2}$	Full load.
Efficiency with A	80·0	89·9	97·2	97·4
,, ,, B	43·4	71·5	93·5	95·6

The above example illustrates the necessity of makers stating the alternator used in the test and the height of the centre of gravity of the wave produced by it at the given effective voltage. They ought to know some simple method of doing this ; otherwise, their tests are of very little value to consulting engineers.

Analysis of Dr. Fleming's Test on a 6-Kilowatt Hedgehog Transformer.—This test was chosen, as it illustrates that the formulæ given above apply to open iron circuit transformers. Also, as there is considerable magnetic leakage, the calculations were made first by neglecting leakage altogether, and then taking it into account. The comparison of the two sets of calculations is instructive, as it shows that we may neglect leakage in the efficiency formula, but that large errors are introduced by neglecting in it the others.

* Swinburne "Hedghog" Transformer. No. 601. Power, 6,000 watts. Current used in test supplied by the London Electric Supply Corporation at a frequency of 83. The average height of the centre of gravity of the E.M.F. wave when the effective voltage is 2,400 is about 1,350, hence it is not unlike the rounded curve produced by the Wechsler machine used by Dr. Roessler.

Primary volts 2,400.

Primary circuit resistance = 7·93 ohms (measured hot).

Secondary circuit resistance = 0·0151 ohm (measured hot).

$$n = \frac{E_2}{V_1 - RA_0\cos\phi_0} = \frac{1}{23{\cdot}53} \; ; \; Q = R + \frac{S}{n^2} = 16{\cdot}3.$$

(To be concluded).

CARBONS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.†

BY FRANCIS JEHL.

(Continued from page 649).

The manner in which a waggon is placed in the tunnel without interrupting the draught is best understood from the diagram shown in Fig. 49. Here T_1 represents that part of the tunnel that contains the waggons in which the goods have already been carbonised, and, as seen, its end is open so as to permit the air to enter that is fed to the fire in the furnace F. T_2 is the part of the tunnel that contains the unfinished carbons or electrodes, and the arrow shows the direction in which the waggons move. The rails are indicated by r, and the turn tables are placed at t. G shows the positions of the generators, and C that of the chimney. At d there is a sort of damper or sliding door made of sheet iron, which, when slid into the tunnel, covers its whole cross-section, and at e there is a ordinary tight-fitting door, also of sheet iron.

At P there is an apparatus which may either be a sort of large, long screw or a suitable hydraulic machine that can be used from time to time to push the train of waggons that are in the tunnel. When the contents of a waggon have been carbonised in the furnace F, the apparatus P is so actuated that the waggons in the tunnel are moved one space further, which act delivers a finished waggon at the end T_1, while at the other end room is made for a waggon to be added. A waggon that has been newly packed with fresh goods is then pushed from the packing department on to the turn table at the T_2 end of the tunnel, and at the same time the sliding door d is pushed in so that it cuts off the part c. The door e is then

* "Experimental Researches on Alternate-Current Transformers." By Dr. J. A. Fleming, F.R.S. *Journal* of the Institution of Electrical Engineers, Vol. XXI., p. 649.

† From a forthcoming book to be published by *The Electrician* Printing and Publishing Company (Limited). All rights reserved.

Digitized by Google

opened and the waggon is pushed in, after which *e* is closed again and the sliding door drawn back. By this simple means it will be seen that waggons can be moved into the tunnel without interrupting the draught, &c.

The advantages the writer claims for his furnace system for the carbon industry are the following:—

There is a large economy in fuel while the greatest possible effect is obtained. The heat contained in the finished articles is taken up by the air used for combustion, which cools them gradually. The heated gases as they leave the furnace heat up a regenerator with a large surface, and after leaving the latter the hot gases slowly and gradually heat up the fresh carbons.

There is a decided advantage in not having a large network of passages and flues, as is necessary in the chamber system, &c., and thus the gas from the generator arrives in the furnace very hot, whereas in those systems where it has to travel long distances it cools down considerably, which means less economy in fuel. In fact the absence of networks of passages, complicated systems of chambers, &c., lessens the cost of the building and maintenance of the writer's system. In the tunnel system there is only one set of valves and dampers while in the chamber or ring system there is a set for every chamber or division, so that the chances of gas escaping is reduced to a minimum in the writer's system, while the handling gives less work than in other systems. Also there being but one chamber in which combustion takes place it can always be maintained at a high temperature; in the other systems the chambers must first get heated up.

The advantage, in a continuous system, of having a regenerator like that shown in Fig. 46, gives us a means with which the fire can be kept up for any length of time and always at a high intensity, while the direction can be reversed from time to time so that the action of the flames and heat

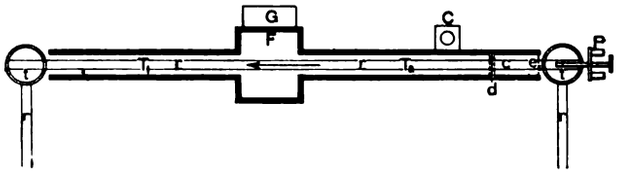

Fig. 49.—Diagram of Jehl's Tunnel System of Furnace.

will produce an even and well-distributed effect on both sides of the retorts and cases that contain the carbons. This cannot be produced in the other systems. This method of changing the direction of the fire from time to time always furnishes us with a well-heated regenerator, and is much used in steel manufacture where only a very high intensity of heat can be used; so that in adapting the same for carbonising carbons and electrodes the more ideal requirements can be obtained. Large electrodes need a very high intensity of heat for a considerable length of time, so that the heat can penetrate into the interior of the carbon mass. This takes time, as carbon is a very bad conductor.

The advantages in handling the carbons, &c., in the writer's system save time and labour, as the carbons and electrodes can be packed in the packing department on the waggons direct, and the finished goods can be delivered into the receiving department. In the other systems the carbons must be packed, and then brought to the furnace, placed in the chambers; the entrances of the latter must always be sealed up with fire-bricks, which are removed again when the chamber is emptied. All this extra work is not necessary in the system described in Figs. 46 to 49. Of course, in this system we have the expenses of the waggons, but their cost is more than balanced by the less cost in building a simple tunnel—one furnace with hardly any length of passages.

A convenient and cheap method of packing electrodes, &c., on the waggons can be effected by means of pieces made of the best fire-clay (chamotte), as shown in Fig. 50. Here pieces similar to *a* serve for the ends, and pieces like *b* are placed between the ends of a trough that is constructed on the waggon. In the waggon W_2 (Figs. 47 to 48) this method of packing is shown. Here *x* indicates fire-bricks that are laid at even lengths, so as to support the trough, while at the same time passages are formed through which the flames and heat can pass. On these fire-bricks pieces similar to those shown in Fig. 50 are laid, their sides being smeared up smooth with fire-clay in order to keep the contents of the trough so formed from burning. In the trough a few fire-bricks are also placed to support the cover, which consists simply of fire-clay slabs. A good bed of carbon dust is placed in the trough, on which the electrodes, &c., are laid, and they are then covered up again with carbon dust, on which the slabs are then placed. In a similar manner four or five such troughs are laid on a waggon, so that there are many passages, as shown in the Figs. 46 to 48, through which the flames and heat can play, and the electrodes are evenly carbonised. It will be seen that such a method of making large troughs is much cheaper than employing troughs made of one piece, for when such a trough breaks it is of no value; while, when a piece as shown in Fig. 50 breaks, it can be replaced at little cost. It is also possible to have such pieces made thinner than can safely be made when whole troughs are made.

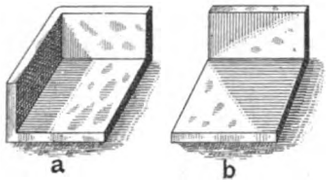

Fig. 50.—Forms made of Fire-clay for packing Carbons and Electrodes.

In Fig. 51 we have a view of a trough made in one piece, as is sometimes used in carbon factories, and to which a cover is provided. These troughs often break, and especially at or near the bottom, as the bottom is generally made much thicker than the sides.

The writer proposes to have such troughs made without bottoms, which will cost much less, while at the same time they will stand the action of the fire better than those with bottoms. The first one is then laid in the waggon and filled with sand; on the top of this another bottomless trough is placed and packed with electrodes; then another, and so on, as shown in Figs. 47 and 48, at waggon, w_1. This method affords also ample passages for the heat and flames. Instead

Fig. 51.—Fire-clay Trough.

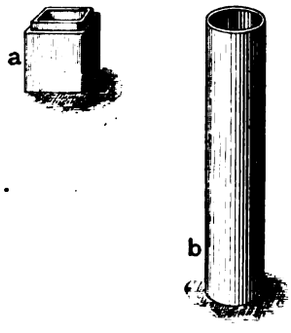

Fig. 52.—Fire-clay Box and Retort.

of using such a form for the lower row, fire bricks can be laid on which a slab rests, on which slab the troughs can be placed, while the top one is, of course, also covered with fire-clay slabs. It will be seen that many good ways can be found by which the carbons can be easily packed on the waggons. In Fig. 52, *a* represents another fire-clay box used sometimes for brushes, &c. These boxes can also be made bottomless, so that they can be placed to fit one upon another, so as to make a long retort. Instead of square forms, round ones are also often used; *b* represents the retorts mostly used by carbon manufacturers for electric light carbons, and it will be seen that if such retorts are constructed from two or three pieces they will be cheaper than when made in one piece. These large retorts often break, and their cost is a considerable item in the expenses of a carbon factory.

(To be continued.)

THE HISSING OF THE ELECTRIC ARC.*

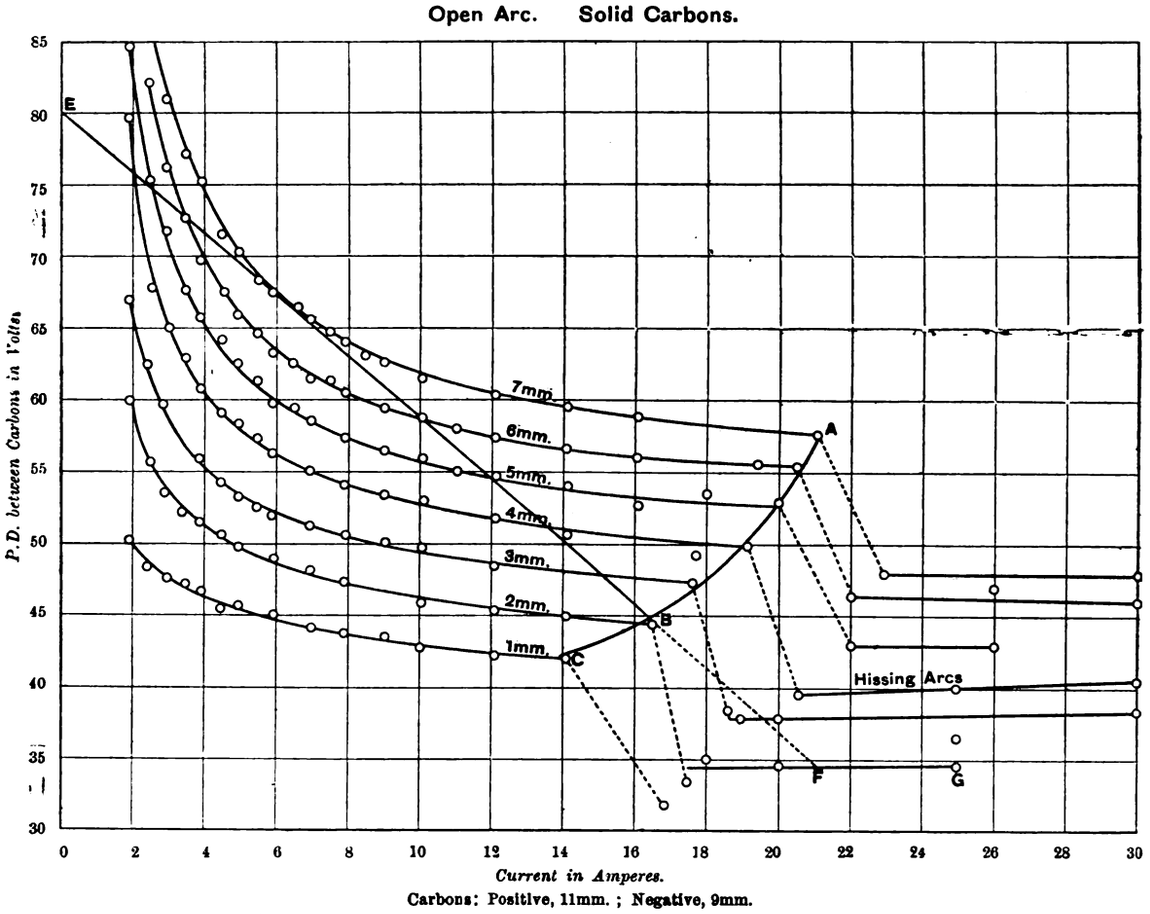
BY MRS. AYRTON.

There are three ways in which any change that takes place in the electric arc may manifest itself: (1) by giving out sounds of various kinds or by becoming silent; (2) by changes in its electrical measurements; and (3) by an alteration in the appearance of the crater, the arc and the carbons. Only two of the many and varied sounds given out by the *direct current open* arc seem to possess much significance—the hum and the hiss—and the causes of these are evidently connected with one another, for the hum never occurs except when the arc is on the point of hissing, or has just been hissing, although it is quite possible to make an arc hiss and become silent again without any hum being heard either before or after. It is proposed, in the present Paper, to discuss the arc as it passes from silence to humming, and from humming to hissing, but, as the changes that occur when the silent arc begins to hum make themselves perceptible to eye and ear only, and do not sensibly affect the electrical measurements, silent and humming arcs will be included under one head in the portion of the Paper dealing with those measurements. It is, however, to the comparatively unexplored region of the direct-current *hissing* arc that I desire to particularly direct your attention this evening.

Some of the electrical measurements of the arc burning between two *solid* carbons 11mm. and 9mm. in diameter are shown in Fig. 1, in which the curves connect the P.D. between the carbons with the length of the arc for several constant lengths of arc, both silent and hissing. It is important to bear in mind that before each observation was made the current and length of arc were kept *rigorously* constant for a sufficient length of time for the carbons to take their characteristic shape for that particular current and length of arc, and long enough, therefore, for the P.D. to have become constant also. Such an arc I propose to call a *normal* arc, as contrasted with one arrived at in a haphazard fashion by suddenly giving the current some particular value and the arc some particular length, and making observations without giving the carbons time to acquire their proper forms. All the lines to the left of the curve A B C represent silent arcs, while immediately to the right of this curve are dotted lines denoting a period when the arc is in the unstable condition that always divides the silent from the hissing arc; and still further to the right are the lines representing the hissing arc. As we are only dealing with hissing and humming arcs, and with the silent arcs that are near hissing or humming, we need only discuss that part of Fig. 1 that is to the right of the line representing, say, 12 amperes, for that part includes all such arcs for each of the constant lengths.

An examination of these curves shows that with the carbons used, and with what I have called the *normal* arc, the following results are met with:—(1) When the length of the arc is constant and the arc is silent, it may be made to hiss by increasing the current sufficiently. (2) The largest current that will maintain a *silent* arc is greater the longer the arc. (3) When the arc begins to hiss, the P.D. suddenly falls about 10 volts and the current suddenly rises 2 or 3 amperes. (4) When the current is constant and the arc is silent, *shortening* the arc will make it hiss. (5) For the hissing arc, the P.D. is constant for a given length of arc, whatever the current.

It was Niaudet* who, in 1881, first observed the fall of about 10 volts in the P.D. between the carbons at the moment that hissing began, and, although, perhaps, there is even yet a lingering notion that it is only when an arc is short that it can hiss,



Carbons: Positive, 11mm.; Negative, 9mm.

FIG. 1.—Curves connecting P.D. and Current for Constant Length of Arc.

I find that as far back as 1889, Luggin† showed that, however long an arc might be, it would still hiss were the current increased sufficiently. At the Congress at Chicago, in 1893, Prof. Ayrton‡ first drew attention to the region of instability, or rather, the region of blankness (notice the dotted portion of Figs. 1 and 2), corresponding with the impossibility of maintaining any *normal* arc with a particular range of current for each length. At the same time he pointed out in Fig. 2, shown at Chicago, that whether the P.D. was descending as the current increased for, say, a 4mm. *silent* arc, or was ascending for, say, a 0·5mm. *silent* arc, it became quite constant for wide variations of current with a *hissing* arc. And, lastly, by a comparison of Fig. 2 with Fig. 3 he brought out the fact that the largest current that would flow silently with any given length of arc was increased by using thicker carbons. For the carbons in Fig. 3 have about twice the diameter of those in Fig. 2, and, while the largest silent current for, say, the 2mm. arc in Fig. 2 is 15·5 amperes, that for the same length of arc in Fig. 3 is about 49 amperes, or more than three times as great.

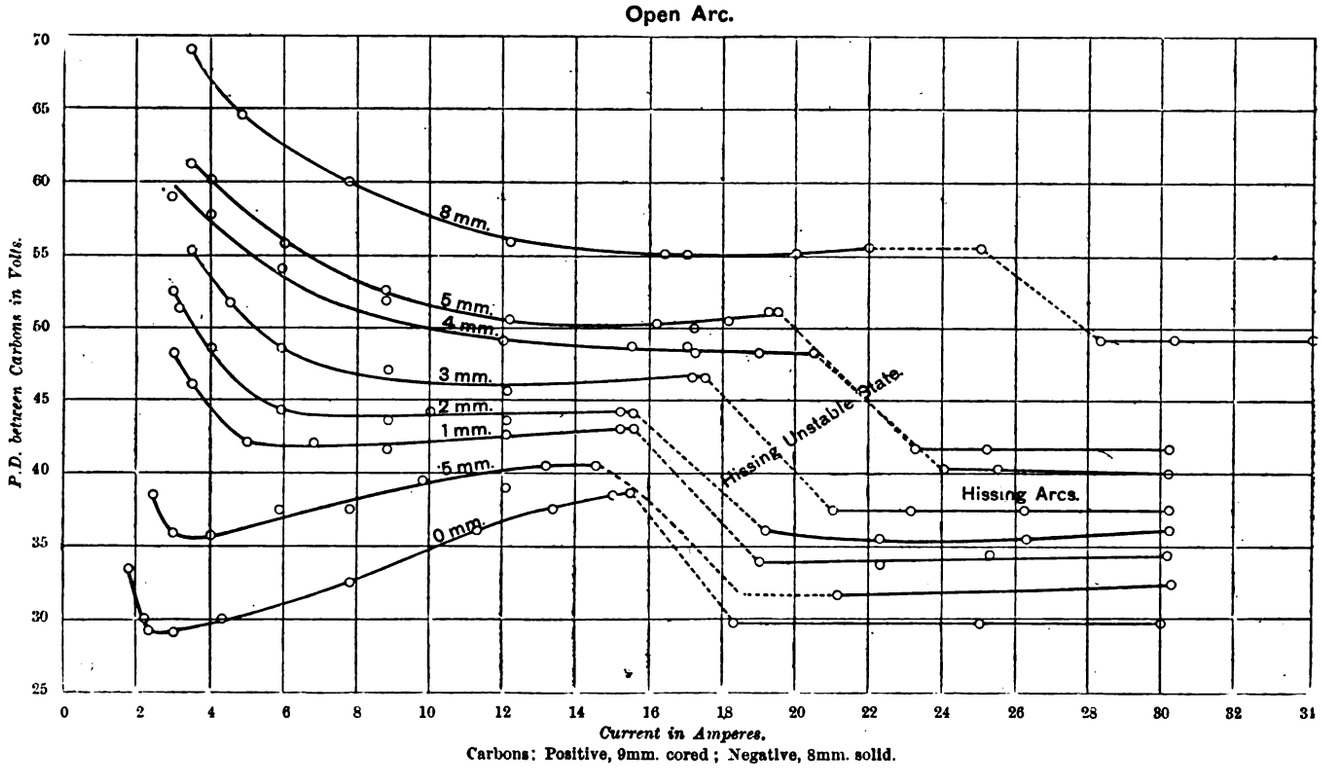
Returning now to the subject of the dotted lines in Figs. 1, 2, and 3, it is plain that these divide the curves into two perfectly separate parts, governed by different laws. For to the left of the dotted part the lines are all curved, and curved differently according as solid or cored positive carbons are used, showing that with silent arcs the P.D. varies as the current varies, and



Carbons: Positive, 9mm. cored; Negative, 8mm. solid.

FIG. 2.—Curves connecting P.D. and Current for Constant Lengths of Arc.

that the law of variation is different with solid and cored carbons. To the right, on the other hand, the lines are all straight, and more or less parallel to the axis of current, whether the positive carbon is solid or cored, showing that with *hissing* arcs the P.D. is the same for a given length of arc and a given pair of carbons, *whatever* current is flowing, and that this law is true whether the carbons be cored or solid. In fact, some complete and sudden break-down appears to occur when hissing begins, upsetting all the

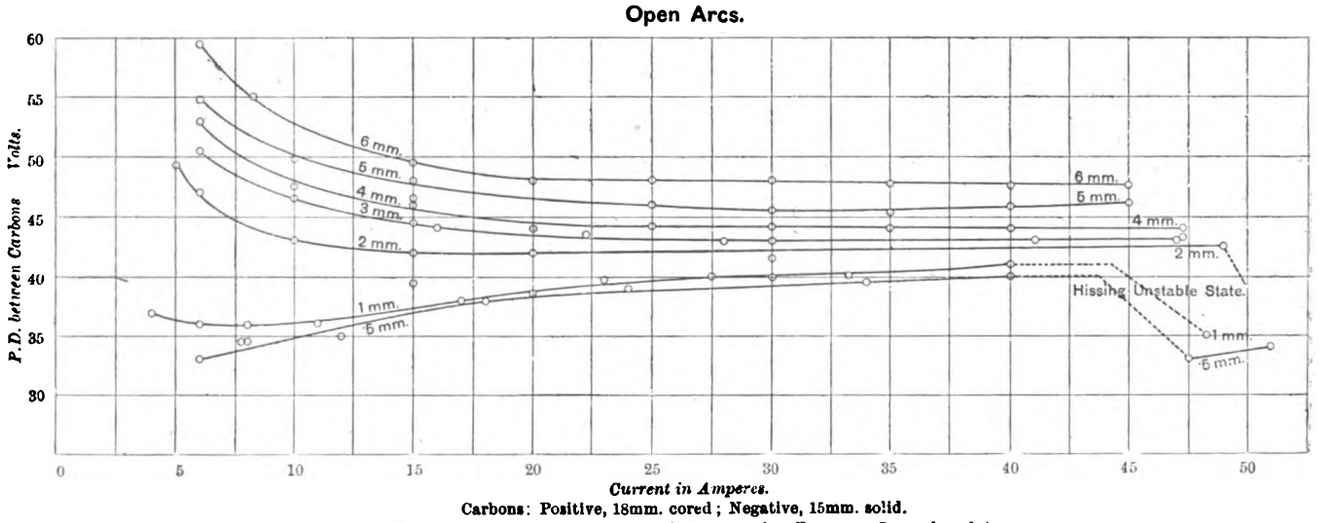
therefore, the arc is really hissing. On examination of Fig. 1, the points of which were obtained experimentally with much care, it is seen that the hissing points lie well on the curve A B C, the equation to which I have shown elsewhere* to be

$$V = 40{\cdot}05 + \frac{2{\cdot}91 - A29{\cdot}02}{10{\cdot}54 - 0{\cdot}416A} \quad \ldots\ldots \quad (1)$$

where V is the P.D. between the carbons in volts, and A is the largest silent current in amperes. Or, expressing the P.D. in terms of l, the length of the arc in millimetres, instead of in terms of the current at the hissing points, we have

$$V \quad 40{\cdot}05 + 2{\cdot}49l \quad \ldots \quad (2)$$

which shows that at the hissing points any given increase in the length of the arc causes an increase in the P.D. between



Carbons: Positive, 18mm. cored; Negative, 15mm. solid.

FIG. 3.—Curves connecting P.D. and Current for Constant Lengths of Arc.

laws that have governed the arc while it was silent, and bringing the behaviour of cored and solid carbons into accord.

Thus, our subject divides itself quite naturally into two distinct portions, the one dealing with the arc when the breakdown is imminent, but before it has actually occurred—dealing, that is to say, with the points at which the current is the largest that will flow silently—the *hissing points*, as I shall call them; and the other dealing with the arc after the breakdown has occurred, and when,

the carbons that is simply proportional to the increase of length. That is to say, for every millimetre that is added to the length of the arc, 2·49 volts is added to the P.D. between the carbons at the hissing point. From the above two equations I deduced the third, viz.:—

$$l = \frac{1{\cdot}17A - 11{\cdot}66}{10{\cdot}54 - 0{\cdot}416A} \quad \ldots\ldots \quad (3)$$

* *The Electrician*, 1896, Vol. XXXVI., p. 541.

Digitized by Google

nd pointed out that, since l was infinite when $10{\cdot}54-0{\cdot}416A=0$, r when $A=25{\cdot}3$ amperes, no current greater than 25·3 amperes ould maintain a normal *silent* arc, however long it might be made with the particular carbons used. Hence we may gather that *for each pair of carbons the current that will sustain a normal silent arc has a maximum value, and that any current greater than this will make the arc hiss, however long it may be.*

To turn, now, to the arc when hissing has actually begun. It has already been shown that *when the arc is hissing, the P.D. between the carbons is constant for any given length of arc, and is, therefore, independent of the current*; but no law has yet been given connecting the P.D. between the carbons with the length of the arc when hissing. This can now be found from Fig. 1, by plotting the mean P.D. between the carbons for each length of arc when it was hissing, with the corresponding lengths of arc. In this way we get a straight line, the equation to which is

$$V=29{\cdot}25+2{\cdot}75l \quad . \quad . \quad . \quad . \quad . \qquad (4)$$

How far equation (4) really sums up the facts may be seen from Table I., which gives the mean value of the observed P.D. between the carbons for each length of hissing arc, the P.D. calculated from equation (4), and the difference between the two.

Table I.—*Hissing Arcs. Mean P.D. between Carbons for Different Lengths of Arc compared with same P.D. calculated from Equation (4).*

Carbons: Positive, 11mm. solid; Negative, 9mm. solid.

Length of arc in millimetres.	Mean P.D. between carbons in volts.	P.D. calculated from equation (4)	Difference in volts.
1	32·0	32·0	0
2	34·4	34·75	−0·35
3	37·8	37·5	+0·3
4	40·0	40·25	−0·25
5	43·0	43·0	0
6	46·5	45·75	+0·75
7	48·0	48·5	−0·5

Equation (4) shows that, *with the hissing as with the silent arc, a straight line law connects the P.D. between the carbons with the length of the arc.*

There is, however, this vast difference between the law for silent and that for hissing arcs—viz., that for silent arcs the law only holds for constant currents or for the currents at the hissing points, whereas for hissing arcs it holds *whatever the current may be.* Thus, while for silent arcs the constants which correspond with the terms 29·25 and 2·75 in equation (4) are constant only for each separate current, and change when the current changes, with *hissing* arcs they remain the same *whatever* the value of the current may be. For instance, the equation equivalent to equation (4) for a normal silent arc with a current of 4 amperes is $V=41{\cdot}79+4{\cdot}71l$, and with a current of 12 amperes it is $V=39{\cdot}85+2{\cdot}95l$; but with the hissing arc the equation is $V=29{\cdot}25+2{\cdot}75l$, whether the current be one of 20 amperes or of 50, *and whether the arc be normal or not.* This brings me to the reason for the great importance of distinguishing between arcs that are normal and those that are not. We have seen that, with normal arcs of any given length, hissing only starts when all the silent arcs have been used up, as it were; that is to say, when the current is *greater* than it can be with any silent arc of the same length. But with a *non*-normal arc of 2mm. I have been able to produce hissing with a current of 11 amperes, and to have a silent arc burning with a current of 28 amperes, the same carbons being used in each case. This apparent anomaly will be fully explained later, when we go into the causes that produce hissing.

We are now in a position to find the law connecting the length of the arc with the change that takes place in the P.D. between the carbons when hissing begins. For if we call V the P.D. between the carbons at the *hissing point* with any given length of arc l, and V′ the same P.D. when the same length of arc is hissing, then from equations (2) and (4) we get

$$V-V'=10{\cdot}8-0{\cdot}26l \quad . \quad . \quad . \quad . \qquad (5)$$

which shows that *the longer the arc the less does the P.D. between the carbons diminish when it changes from silence to hissing.*

In 1889, Luggin* found, by measuring the fall of potential between each carbon and the arc, that the principal part of the diminution of P.D. caused by hissing took place at the junction of the positive carbon and the arc. About three years ago, not then having come across any account of Luggin's experiments, I made some of the same sort myself, and obtained the same result. I used two solid Apostle carbons 11mm. and 9mm. in diameter, and the third carbon for placing in the arc was 3mm. in diameter. This last was somewhat thick, but it burnt well to a point in the arc, and thinner carbons burnt away too rapidly with the current I used—25 amperes—to give good measurements. The P.D. between the positive carbon and the arc was found by placing the third carbon in the arc as close as possible to the positive carbon, and measuring the P.D. between the two with a very high resistance voltmeter. This was easily done when the arc was hissing, but was impossible when the largest silent current was flowing, for then the mere insertion of the third carbon was sufficient to make the arc hiss. Accordingly, the P.D. between the positive carbon and the arc when the largest *silent* current was flowing has had to be calculated from the formula I gave at the meeting of the British Association† last year for calculating that P.D. with *any* silent current, viz., $V=31{\cdot}28+\frac{9+3{\cdot}1l}{A}$.

* *Wien Sitzungsberichte*, 1889, Vol. XCVIII., p. 1,192.

Carbons: Positive, 11mm. solid; Negative, 9mm. solid.

Length of arc in millimetres.	Diminution of P.D. between carbons due to hissing.	Diminution of P.D. between positive carbon and arc due to hissing.
1	10·1	7·7
2	9·9	7·0
3	10·5	6·6
4	8·9	6·7
5	9·1	4·6
6	9·6	5·4

In Table II. two sets of currents are dealt with, viz., the largest silent current for various lengths of arc, and a hissing current of 25 amperes; and, for each of these sets of currents and lengths of arc, two P.D.'s are given, viz., the P.D. between the main carbons, and the P.D. between the positive carbon and the arc itself. Now, in order to compare the change in the P.D. between the main carbons caused by hissing, with the corresponding change in the P.D. between the positive carbon and the arc, we must subtract column 4 of Table II. from column 2, and column 5 from column 3, and compare the differences. These difference are given in Table III. Thus for the lengths of arc dealt with, hissing causes a mean fall of about 9·7 volts in the total P.D. between the main carbons, and a mean fall of about 6·3 volts in the P.D. between the positive carbon and the arc. Hence of the whole diminution of the P.D. between the carbons caused by hissing, about two-thirds takes place at the junction of the positive carbon and the arc.

Further, my experiments showed that very little of the remainder of the diminution, if any, was due to a fall of the P.D. between the arc and the negative carbon; therefore this remaining diminution must be attributed to a lowering of the resistance of the arc itself. We may sum up these results as follows:—*Of the total diminution of the P.D. between the carbons caused by hissing, about two-thirds takes place at the junction of the positive carbon and the arc, and the remaining third seems to be due to a lowering of the resistance of the arc itself.* From Fig. 1 it might be supposed that, given the length of the arc, the increase of current that abruptly occurs as the arc starts hissing was as definite for that length of arc as the diminution in the P.D. And this, for a long time, I imagined to be the case. But, while trying to find out what law connected the smallest hissing current with the length of the arc, I saw that the value of that current really depended on the circuit *outside* the arc. For, let E be the E.M.F. in volts of the generator, which we will assume to be constant and independent of the current; r, resistance in ohms of the whole circuit *outside* the arc; l, length of the arc in millimetres; A, largest silent current in amperes; V, corresponding P.D. between the carbons in volts; A′, smallest hissing current in amperes; V′, corresponding P.D. in volts, then $E=V+Ar$ and $E=V'+A'r$; therefore, $\frac{A'-A}{V-V'}=\frac{1}{r}$, that is, the sudden increase of current when hissing begins equals

† *Report of the British Association*, 1898, p. 805.

Digitized by Google

the product of the sudden diminution of the P.D. into the conductance of the circuit outside the arc. Again, $\frac{A'}{A}=\frac{E-V'}{E-V}$ or $A'=\frac{E-V'}{E-V}A$. But for a given hissing point, for example, B (Fig. 1), V, V', and A are all constants; therefore, for such a point A' depends simply on E. In fact, for a fixed point B and a fixed line F G, the position of the point F merely depends on the slope we give to the line E B F; that is, on the point of the axis of P.D. we select for E. And a consideration of the figure shows that the distance between this point E and the axis of current measures E, and the E.M.F. of the dynamo. Consequently it now appears that the dotted lines in the unstable region constitute records of the particular E.M.F.'s the dynamo was made to give on the various days when the experiments were made with the different lengths of arc, several years ago. *Hence, when the largest silent current changes to the smallest hissing current for the same length of arc, the value of that smallest hissing current depends on the E.M.F. of the generator only.* Thus, it is possible, by choosing suitable E.M.F.'s, to make the sudden smallest hissing current have any value greater than that of the largest silent current for the same length of arc. It is evident from Fig. 1 that the smaller the E.M.F. of the generator, the larger will be the value of the smallest hissing current, for the lower down will E be on the axis of P.D., and therefore the farther will the point F be along the line F G. This explains a circumstance that puzzled me greatly when it happened, but which is now perfectly comprehensible. Some years ago I was using accumulators to maintain an arc, and employing as small a number of cells as possible. I was able to have quite a moderate current as long as the arc was silent, but as soon as it began to hiss, the current rushed up to some huge value which would inevitably have ruined the cells, if I had not had a cut-out arranged to break the circuit. Why the first hissing current should be so much greater than I was accustomed to find it with the dynamos I ordinarily used, I could not imagine, but the reason is now perfectly obvious. The hissing current was so great simply because the E.M.F. of the cells was so small, and had it been possible to maintain a silent arc without any resistance in the outside circuit except that of the cells, which is what I was trying to accomplish, I might, except for the cut-out coming into operation, have had practically an infinite current when the arc began to hiss.

(To be continued.)

ELECTRIC TRACTION AND ITS APPLICATION TO SUBURBAN AND METROPOLITAN RAILWAYS.*

BY PHILIP DAWSON.

(Concluded from page 765.)

Having tried to show the advantages which electric traction possesses, as regards the possibility of increasing the frequency of the trains without decreasing the factor of safety, namely, the distance between two trains, it may be advantageous to see how, from an economical standpoint of generating power, electricity is a cheaper method of operation than steam locomotives. An electrically-driven train only requires one man instead of two to drive it, and when the train is not running no power is consumed and no coal or water wasted. Steam locomotives, it is well known, use but very little less coal and water when they are standing still than when they are running, and are much less economical, consuming, as they do in America, from 5lb. to 6lb. of coal per indicated horse-power. On main line English roads it is stated that 3lb. to 4lb. are consumed, and, taking an average power of 400 H.P. per locomotive, and a train, plus engine, weighing 250 tons at a speed of 40 miles an hour, we get at the most economical rate about 0·65lb. of coal per ton mile, or, compared to the electric power required by electric traction, 1lb. of coal per Board of Trade unit required, which is enormous—under favourable conditions it would not take much over 3lb. of coal to give one Board of Trade unit at the switchboard. A properly designed electric station, with large units, would probably never consume more than 2lb. of coal per indicated horse-power hour, or 2·65lb. per kilowatt hour at the awitchboard, and engines of the size of 4,000 to 6,000 H.P. would be guaranteed to consume not more than 12lb. of steam per indicated horse-power hour. A large station would fully justify a comparatively large initial expense in coal handling and stoking machinery, and the location of the station could be chosen so as to be most advantageously situated as regards both coal and water, the coal without being handled being taken from either the ship's hold or the railway truck, conveyed automatically to the cold stores, and from thence automatically to the fires, the ashes being conveyed away automatically as well. In such a station but very few men would be required, and the cost of power could be reduced below one halfpenny per Board of Trade unit, including expenses of every kind.

* Paper read before the Society of Arts, March 22, 1899.

Comparing again the coal consumption per train mile on large English main line railways, which varies from 35lb. to 58lb. of coal per train mile, we get a coal consumption of from 0·146lb. to 2·32lb. per ton mile, corresponding to 28·12lb. to 46·4lb. per Board of Trade unit, required to be generated at the power-house. The following results actually obtained with slow-speed Corliss type engines and standard American railway generators may be of interest:—Total coal consumed, Brooklyn City Railway Co. per Board of Trade unit, 3lb. Total cost, everything included, of Board of Trade unit at switchboard, 0·5195 cents. (about one farthing). Cost of coal per unit, 0·2307 cents, about 0·166 of a penny; Union Traction Co., Philadelphia. Poorest coal, 3½lb. consumed per Board of Trade unit at switchboard. In another case cost of coal, 0·272 cents per Board of Trade unit at switchboard, about 0·186 pence. Total cost of unit, all included, 0·591 cents, about 0·296 pence. Coal consumption in another case with Corliss engine, average for one year, per indicated horse-power hour, 1·65lb. to 1·76lb. What good slow-speed Corliss engines, properly designed for railway work, compared to other engines, mean are shown by the fact that by such a change in a large American station the coal consumption was reduced from an average of 8·3lb. to 4·9lb. of coal per car mile.

From a series of figures obtained from the various Chicago electric overhead lines, from 0·116 to 0·135 Board of Trade units are required at the switchboard to drive the trains, the average speed of the trains being 13½ miles an hour, and the maximum speed obtained varying from 28 to 35 miles an hour. The coal and water consumption, per Board of Trade unit, could not help but be very low, the losses in the step-up and step-down transformers and in the transmission and rotary converters would not be very great, and it would be perfectly feasible to attain an efficiency of 60 per cent. at the motor terminals and of 50 per cent. on the power applied to the car axles. Large engines and large generators and converters are designed so as to take an overload of 25 per cent. for any period of time, and be capable of overloading 50 per cent. for a short time without injury, and by a selection of proper units a very large economy could be attained.

Metropolitan Elevated, Chicago.	
Length of street	36¼ miles.
Average distance between stations	1,600 feet.
Time interval between consecutive trains	2½ minutes.
Average speed in miles per hour	13 miles.
Maximum speed	28 miles.
Total rated power of generating station	5,000 kw.
South Side Elevated, Chicago.

Average distance between stations	4,280 feet.
Maximum speed per hour	43 miles.
Average speed	25 miles.
Board of Trade units per ton mile, at switchboard	0·0808
Weight of two-car train	55 tons.

The elevated railroads of New York and Brooklyn have been losing business during the last few years so rapidly that the financial condition of the Brooklyn system is serious, and the return on investment of the New York system much reduced, and is still declining. The elevated railroads of Chicago have never been able to earn a satisfactory dividend. The general introduction of electricity in the Chicago system has greatly improved the Chicago situation, in spite of the competition of the surface trolley lines, which parallel the elevated lines in most cases. The elevated railroad problem is resolved into a discussion of speeds, station frequencies, and relative costs of service. Any railroad of this class which aims to maintain a high schedule must choose a motive power in which the possibilities of rapid acceleration are a maximum, and—all other conditions being equal—should choose that particular motive power which will bring about the quickest acceleration, consistent with due economy. The Manhattan system is a comparatively simple one, with four main through lines, without branches of importance,

Digitized by Google

while the Brooklyn and Chicago systems are composed of trunk lines with branches, involving more or less complicated switching arrangements. Until about a year ago, the three Chicago companies, the Lake Street, the South Side, and the Metropolitan, had independent termini in the business heart of the city. Now, however, the newly constructed "Loop," encircling the business district, is used as a terminus for all three lines and for a fourth, the North Western, now under construction, and all the elevated trains of the city pass round this loop on each trip. The Brooklyn elevated system has lately secured a new terminus on the Manhattan Island side of the Brooklyn Bridge, and experiments are being made with a view to converting the entire Brooklyn system to electricity in the near future. The entire New York system, however, is at present operated by steam locomotives. The little locomotives in use on the New York system weigh 47,000lb., of which 31,500lb. are on the four 42in. driving wheels, and 15,500lb. are on the four 30in. truck wheels. The total wheel base is 193in., of which 60in. is rigid. The cylinders are 12in. in diameter, and have a 16in. stroke. The grate area is 16·5 sq. ft., and the total heating surface is 4,034 sq. ft. There are 154 flues 1½in. in diameter and 75in. long. The standard Manhattan car weighs 29,088lb., has seats for 48, and frequently carries 100 passengers. It is mounted on eight 30in. wheels. The total weight of a 5-car loaded Manhattan train is about 130 tons. The weight on the drivers is 12 per cent. of the total train weight, and, with 25 per cent. adhesion, the maximum drawbar pull possible for the locomotive to exert is 7,875lb.

The electric locomotive car of the Metropolitan Elevated Railway Company, of Chicago, weighs 53,200lb. complete with motors, or 40,000lb. exclusive of motors. It is a standard American passenger car with full seating capacity, about one-half of each platform being taken up with the cab and necessary controlling apparatus. The trail cars weigh 33,000lbs. The seating and standing capacity of both motor and trail cars is approximately 90 passengers. The average 4-car heavily-loaded train will weigh about 100 tons, of which 32·5 tons approximately are on the four wheels of the locomotive's motor truck, and 67·5 tons are in the trail cars. From 30 to 35 per cent. of the entire train weight is available for traction under these conditions, and the maximum drawbar pull possible to exert without slipping of wheels is about 16,250lb. The South Side Elevated Railway Co., of Chicago, is equipped with the Sprague multiple unit system, by means of which two or more cars in a train are equipped with motors and may be operated in unison by a single controller from any point in the train. The company is now operating four car trains, on each of which is a motor truck carrying two motors. The cars weigh about 20 tons each, without load, and about 60 per cent. of the train weight is available for traction.

There are, therefore, three distinct types of elevated railway equipment—the steam locomotive, using 10 to 15 per cent. of the train weight for traction under heavy traffic conditions; the electric locomotive, using 30 to 35 per cent.; and the multiple unit system, using any amount desired up to 60 per cent. of the train weight.

The transportation expenses of the South Side Elevated Railway in Chicago for July, August and September, 1897, when steam locomotives were employed, were 2·8 cents per car mile, while in the same months of 1898 they were 1·9 cents per car mile, or a saving of nearly 0·9 cents, or about 33 per cent.

Metropolitan District, London.

Average speed in miles per hour	13½.
Maximum " "	27.
Minimum time between consecutive trains	2 minutes.
Average time between consecutive trains	3½ to 4min.
Total weight of train	161 tons.
Average carrying capacity	450 passen.
Weight of locomotive	47 tons.
Average distance between stations	2,600ft.
Time required in seconds to reach 25 miles an hour starting from a standstill	30 seconds.

The figures in the above table show at once the great advantage to be gained by electric traction, by means of which speed of 25 miles an hour could be obtained in 10 seconds, and by simple calculation it is easy to ascertain that this would greatly increase the average speed and therefore decrease the time necessary to do the distance.

The characteristic difference between the acceleration curve of a train hauled by a steam locomotive and one driven electrically is that, whereas the acceleration where steam is used as motive power increases at first, slowly following a curve which is nearly tangent to the horizontal or time axis, the acceleration curve in the case of electric propulsion is represented by a straight line rising very rapidly, and forming a very small angle, with a vertical axis.

It may be interesting to mention a few details regarding the two large power stations which are now being equipped in New York, and which will operate the two large tramway systems of that city, namely, the Metropolitan and the Third Avenue. The Metropolitan station is now under construction, and will contain 11 direct connected sets each of 3,500 kilowatts, room for extension being allowed, and a capacity having been foreseen of nearly double that amount. The following gives the particulars of the General Electric Co.'s dynamos which will be used. The machine will have a frequency of 25 cycles per second, at 6,600 volts. It will have 40 poles, and will run a speed of 75 revolutions per minute. It will be of the stationary armature type, the core being built up of laminations 0·014in. thick. Each lamination has two dovetail projections, which fit in corresponding slots in a heavy cast-iron spider. Spaces are left between the laminations at intervals, through which currents of air are driven by the rotating field and circulating by intimate contact with core and windings. The armature winding consists of form-wound coils placed in slots in the core, and retained by wooden wedges, the edges of which fit into recesses in the teeth. The field frame consists of a cast-steel ring, supported upon a cast-iron spider; to this are bolted laminated cores of sheet iron, the pole-pieces of which project over and support the copper field windings. The field winding consists of copper strip wound on edge with paper insulation between turns. The insulation is such as to stand a test of 4,000 volts alternating between the winding and the core. The exciting E.M.F. is 125 volts. The collecting rings are of copper, and carbon brushes are used. The armature winding is tested to 12,000 volts alternating. The temperature rise of the machine after 10 hours' run at full load is well under 40°C. The efficiencies are as follows:—

1¼ load	90 per cent.	½ load	92·5 per cent.
Full load	95·5 "	¼ load	88 "
¾ load	95 "	Inherent regulation	9 "

The steam engines which drive these dynamos are cross compound Allis vertical engines, 46in. high and 86in. low pressure cylinders, and 60in. stroke. They will develop 4,900 I.H.P. at the rated economical load, and will be able to work continuously at 6,000 H P. if required, and for a short space of time they are to be able to work at 7,000 H.P. The crank shaft is of solid steel, bored and forged, with a hole 16in. diameter the entire length, and it is 37in. in diameter where the wheel and armature are located. The diameter of the shaft in the bearings is 34in., and the length of the bearings 60in. The fly wheel will have cast steel centres, and the rim will be built up of steel plates riveted together. The rim will weigh 225,000lb., and the engine itself, complete, about 600 tons, and it is believed that as good results as 12½lb. of steam per indicated horse-power will be easily obtained. There will be several sub-stations in which will be located step-down transformers of 300 kilowatts each, which will lower the voltage from 6,600 volts to 350 volts. At this pressure the current will enter rotary converters of 900 kilowatts each, and will be delivered in the shape of a continuous current of 500 volts to the tramway system. This company operates some 250 miles of tracks and carries approximately 250,000,000 passengers every year.

The Third Avenue Road is now engaged in equipping all existing horse and cable lines with electric traction, and for this purpose has just given out a contract for a power station which will eventually contain 16 3,000 kilowatt generators. The generators will be very similar to those described above, and are being built by the Westinghouse Company, who are the sole contractors for the whole work. The engines will be Marine type, vertical, and are being built by the Westinghouse Machine Company. Sub-stations with rotary transformers will be used, as in the case of the Metropolitan system.

To give an idea of what may be done as regards power transmission, the following few figures may be useful. The first attempts at this class of work were made during the Frankfort Exhibition of 1891, 300 H.P. being satisfactorily transmitted a distance of 106 miles with a pressure of 30,000 volts. Since that time electrical power transmission has largely increased, and the results obtained have been very satisfactory; 4,000 H.P. at the present moment are regularly transmitted a distance of 85 miles to the city of Sacramento, California, at a pressure of 30,000 volts, where they are transformed into low-pressure three-phase and continuous current for lighting, power and traction purposes. At Teluride, Utah, 1,000 H.P. are transmitted 55 miles, at a pressure of 40,000 volts; 4,500 H.P. are transmitted a distance of 40 miles to Salt Lake City, at a pressure of 15,000 volts; 1,400 H.P. are being transmitted 35 miles to Fresno, California, at a pressure of 11,000 volts; 2,000 H.P. are being transmitted 30 miles to West Kootenay, British Columbia, at a pressure of 20,000 volts; 10,000 H.P. are being transmitted from Niagara to Buffalo, a distance of 22 miles, at a pressure of 10,000 volts. All the plants are working and giving satisfaction, and have nothing experimental about them, and there are hundreds more such.

In the designing and carrying out of a large system there are three points which are frequently overlooked, and which may cause a disastrous failure. These are good and adequate bonding; thoroughly good insulation, both mechanically and electrically; and trucks suited for the work for which they are intended. As regards the bonding, the bonds used should be flexible, but, at the same time, should contain no solder or brazed joint, and they should be expanded against the side of holes drilled in the web or

Digitized by Google

foot of the rail, and held in place by pins. Bonds of this description, when properly applied, can be absolutely relied upon, the contact resistance of the bond with the rail not being greater than the resistance of the solid bond. With regard to the third-rail insulators, very good results are obtained by using insulating bolts screwed into base plates which are fixed to the sleepers, cast-iron chairs being fixed to the head of the bolts to hold the rails.

ELECTRICITY WORKS ACCOUNTS.

Chelsea Electricity Supply Co. (Limited).

Our two analyses this week are of the accounts for 1898 of the Chelsea and House-to-House Companies. Both concerns commenced business in 1889, and have, therefore, been in operation over nine years.

Since 1897 the remaining portion of the authorised share capital of the Chelsea Company has been paid up, the total being £200,500. An additional £32,120 has been raised on Four and a-Half per Cent. Debenture stock, the total from this source being now £92,120. The capital expended has reached £332,291, or at the rate of about £147 per kilowatt of generating plant in the stations. During the year 226 additional consumers were secured, with the equivalent of 16,062 8 c.p. lamps, thus raising the lamp connection from 96,638 to 112,700—an increase of nearly 12 per cent. The output for the year was 1,220,198 units sold, or about 15 per cent. higher than the output of 1897. The revenue from supply has been kept practically steady at about 5·8d. per unit. The items in expenditure of wages and repairs and maintenance at the station show a decided increase, with the result that the works costs for 1898 are higher by 0·1d. than they were in 1897. This increase has, however, been more than compensated for by economies in management and property charges, so that the total costs and their ratio to the revenue have remained constant.

A working profit of £16,662 was turned, and has afforded an ordinary dividend of 6 per cent. after paying £2,786 as interest, £2,500 to the renewal and depreciation fund, and a 6 per cent. dividend on the Preference shares. The payment into the reserve fund of £12,780 was, as in 1897, made out of the premiums received on share issues. It should be stated that the renewals and depreciation fund account has been charged with £670 to "Renewals of Plant," and in our table the items opposite repairs and maintenance at the station and of the mains are exclusive of this £670. We append a table which is an interesting record of the progress of the undertaking:—

Year.	No. of consumers.	8 c.p. lamp connection.	Output units sold.	Rev.	Gross Profit.	Div.	Plant capacity kw.	Max. load kw.
1889	93	8,730	...	...	...	...	...	...
1890	252	19,580	...	£6,079	£543	...	£66	...
1891	...	27,500	290,458	10,173	1,750	...	449	...
1892	...	34,876	357,162	12,523	4,319	2¼%	...	...
1893	...	40,665	402,848	13,732	6,269	5%	885	...
1894	...	47,286	469,515	15,486	8,096	5%	885	476
1895	715	57,354	577,770	17,165	9,890	5%	1,205	638
1896	972	80,460	813,764	21,355	10,362	5%	1,310	980
1897	1,190	96,638	1,061,970	27,382	14,555	6%	1,860	1,350
1898	1,416	112,700	1,220,198	31,363	16,662	6%	2,260	1,390

House-to-House Electric Light Supply Co. (Limited).

The 1898 accounts of the House-to-House Company give evidence of very satisfactory progress. In the course of the year 861 additional consumers with the equivalent of 13,937 8 c.p. lamps were connected to the mains—an increase in the latter of 21 per cent. A similar and corresponding increase shows itself in the output which was 974,618 units sold as compared with 811,255 in 1897—a rise of slightly over 20 per cent. The average revenue for supply was practically the same as in the previous year, viz., 5¾d. There is a slight rise in the costs, but the fuel charges, in spite of the troubles in the coal trade last year, have dropped and generally there is a practical maintenance of the satisfactory working of 1897.

The tariff is at the rate of 6d. per unit subject to rebate on the following scale in 1898 provided that the consumer's maximum demand in kilowatts does not exceed 0·2 per cent. of the consumption in units during the year:—

On consumption per annum of or above	Discount.	Price charged.
3,000 units.	¼d.	5¾d.
4,000 ,,	⅜d.	5½d.
5,000 ,,	½d.	5¼d.
6,000 ,,	1d.	5d.
10,000 ,,	1¼d.	4¾d.
14,000 ,,	1½d.	4½d.
20,000 ,,	1⅝d.	4¼d.
30,000 ,,	2d.	4d.
50,000 ,,	2¼d.	3¾d.
75,000 ,,	2½d.	3½d.
100,000 ,,	2⅝d.	3¼d.
150,000 ,,	3d.	3d.
250,000 ,,	3¼d.	2⅝d.
500,000 ,,	3½d.	2½d.

We fear that under this scale few consumers will enjoy even a rebate of ¼d. per unit, for there cannot be very many who will each consume 8,000 units annually, equal to £75 per annum. In the last line of the table provision is made for a consumer to buy more than half the units sold during the whole of 1898.

The working profit made during 1898 amounted to £14,066, representing 8·39 per cent. of the mean capital. Out of this profit £4,000 has been carried to the depreciation fund and £1,507 paid in interest on loans. The balance has afforded the payment of a full dividend on the Seven per Cent. Cumulative Preference shares and a dividend on the Ordinary shares of 6 per cent. for the year.

Of the authorised capital of £249,500, £140,635 has been received from the issue of shares and £50,000 has been borrowed on Four and a-Half per Cent. Debenture stock. Up to December 31st last the expended capital amounted to £177,538, representing £122 per kilowatt of generating plant. The following table indicates the progress made since 1889:—

Year.	No. of consumers.	Equivalent lamp connection.	Output.	Plant capacity k.w.	Max. demand. k.w.	Revenue.	Working profit.
1889	78	4,520	...	...	...	...	...
1890	248	13,665	...	300	...	£5,010	£386
1891	373	19,388	247,861	300	250	8,328	2,250
1892	471	23,700	313,484	450	306	10,689	2,837
1893	599	28,429	358,506	550	354	12,064	4,231
1894	755	35,858	400,911	550	410	13,696	6,264
1895	932	44,162	476,714	930	520	15,395	6,841
1896	1,164	55,265	643,693	1,325	658	17,442	9,032
1897	1,416	66,364	811,255	1,410	809	20,811	12,033
1898	1,777	80,301	974,618	1,460	917	24,907	14,066

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Aberdeen (Municipal)	1899 Jan. 6	Kens'gton & Knightsbr' (Co.)	'99 Mar. 3

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co."*

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

The Electrician" is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 6d.	16s. 0d.	8s. 0d.	

"The Electrician" offers exceptional advantages to Advertisers. **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.** *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particular on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I. Price** 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original Illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Geipel and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

RAPID TRANSIT.

A problem which the Americans have long since faced, and in their own fashion have solved, is now being recognised in our own country, viz., the problem of what in America is termed "rapid transit"—the systematic transportation of large crowds of passengers between city and suburbs, or between adjacent cities. There is observable a marked difference in the manner of attacking this problem in different countries, a difference partly arising from divergences in social and even engineering requirements, and partly having its cause in the peculiarities of national character. In America the problem has been solved in a systematic manner, the growth of large cities being attended by the prompt provision of adequately organised methods of transportation. This is seen in the way electric tramways, light interurban railways, and overhead railways in cities, have been developed and engineered. We refer not merely to the abundant existence of these facilities, as contrasted with their paucity in the United Kingdom; the evidence of a careful study of the problem is shown as much in the peculiarities of their engineering design as in the amount of their mileage. To make our meaning clear, let us sketch the main developments of English transportation and contrast these with the characteristics exhibited in American practice. We may preface our remarks by saying it is in no way our purpose to extol American electric traction at the expense of English electric traction; for in the comparatively few places where electric traction has been adopted in this country it compares most favourably with American practice. This, however, is by the way.

In England, it can scarcely be said that the development of transportation facilities has kept pace with the growth of crowded centres of population. Except for its main railway system, which stands *facile princeps* among the railway systems of the world, the United Kingdom, considered as a whole, is barely half civilised in the matter of transportation. The invariable amazement of the American on his first visit to this country is no affectation; it is equalled by the astonishment of the Briton at the converse state of affairs when he visits America. As regards street traffic, our British arrange-

Digitized by Google

ments lack two qualities essential to the provision of good "rapid transit," viz., organisation and the means of attaining a high speed quickly. The omnibus necessarily implies disorganisation; while, wherever the horse is the source of power, neither rapid acceleration nor high speed is possible. Satisfactory organisation implies a frequent and a scheduled service of vehicles between pre-arranged stopping places; rapid transit implies the provision of mechanical motive power capable of producing a high-speed between stopping places not widely separated from one another. And, if all these requirements are lamentably absent from our usual omnibus and tramway systems, so are they far from being conspicuous in our heavier methods of transportation. Whether on the suburban railways or as exhibited on the underground railways of London, the ordinary steam railway train is but badly adapted to the requirements of rapid transit of the kind we are considering. The enormous mass to be set in motion by the locomotive renders it well nigh impossible, and always costly, to provide sufficient power to produce rapid acceleration. Consequently, on these railways the choice of necessity lies between infrequent stoppages and a low mean speed. In either case the service does not satisfy the requirements of the problem. What is needed everywhere, whether in the streets and roadways, or on the suburban and city railways—whether elevated or underground is not relevant to the question—is a frequent service of vehicles, each attaining a high velocity between a series of stopping places situated much nearer together than is usual on English suburban railways, or even on the Inner Circle. This is attainable, in our opinion, neither by vehicles that are not run on rails, nor by any species of mechanically-propelled vehicle the source of energy for which is contained in the vehicle itself. In other words, the only solution practicable, in the present state of engineering, is a system of cars continuously supplied with power from outside; for only in vehicles of this description does it seem possible to obtain that high ratio between the available power and the mass to be moved which the problem necessitates. Speaking of acceleration, by the way, we are not aware that any experiments have been made with a view to determine definitely the amount of acceleration which the human organism will safely or even comfortably stand. The precise circumstances, of course, would naturally affect the limiting value; but what is wanted in the present instance is the figure for the safe acceleration of an individual in a train or tramcar. This figure is much higher than ordinary traction practice, or even than ordinary brake practice. Emergency brake practice occasionally reveals what the human subject will patiently submit to. That a man can stand an acceleration equal to gravity is shown by the fact that mere falling does not injure him; it is abruptly ceasing to fall that does the mischief. In mining practice the cage is not infrequently allowed to fall freely down a considerable part of the shaft. But gravity does not act on a falling man merely as a whole mass; it acts simultaneously and proportionally on every atom of his composition. Railway acceleration acts differently; it starts the man's legs and the exterior part of his body first, leaving his internal economy to catch up afterwards. Hence the serious strain on the internal tissues produced by this form of acceleration when rapid, and the liability to severe—even fatal—injury if the acceleration be extremely large. Exact data, however, appear to be wanting. By acceleration, of course, is not meant only an increase in speed; our remarks apply equally also to a decrease in speed, or to a change of direction on a curve.

Coming to the main point, it is evident that electric traction provides the only method of satisfactorily solving the problem of rapid transit in and between adjacent cities. The precise conditions under which it has done so in America are discussed in the Paper on "Electric Traction and its Application to Suburban and Metropolitan Railways," read by Mr. Philip Dawson before the Society of Arts on the 22nd inst., the concluding portions of which we reprint this week. Inasmuch as the essence of the problem lies in high acceleration and a frequent service of vehicles, it is open to doubt whether, in the electric railways now being constructed in London, the train unit is not somewhat too heavy; also, whether the motor-car principle is not, on these very grounds, preferable to the locomotive-and-train principle. At any rate, one advantage of the motor-car principle is its greater flexibility, as it allows of either long or short trains or separate cars being run, at longer or shorter intervals, to suit the requirements of the hour—a very useful reserve of traffic management in times of emergency. The motor-car principle has proved successful on 90 miles of elevated electric railway at Chicago, and on the Liverpool Overhead Railway in this country. On the other hand, the City and South London Railway system, we believe, has not proved so successful, though the causes appear to be not sufficiently general to condemn the locomotive system. Doubtless, after the various underground electric railways that are being constructed under London have been running for a year or two, sufficiently reliable data will be forthcoming for a better and more certain judgment as to the relative merits of these two methods of electric railway traction.

OBITUARY.

GUSTAV HEINRICH WIEDEMANN.

Germany has lost one of its hardest workers in the realms of pure physics by the death of Prof. G. H. Wiedemann. He was one of those who pursued the study of science in the true spirit of an investigator, out of pure love of his self-imposed tasks, leaving to others the work of applying the results of scientific progress to industrial problems. To our readers, Wiedemann will best be known as editor of the *Annalen der Physik und Chemie*, more commonly known, since 1887, as *Wiedemann's Annalen*, and before that, when it was published by Gren, Gilbert and Poggendorf, as *Poggendorf's Annalen*, This journal has always been the principal organ by means of which the research work of German scientists has been published to the world, ranking on an equal footing with the official publications of the Royal Society in this country and of the Académie des Sciences in France.

Gustav Heinrich Wiedemann was born in Berlin on Oct. 2, 1826, and was the son of a wholesale merchant. He was educated at the Berlin Gymnasium which was then under the direction of Prof. August, and at the age of eighteen he became a student of the Berlin University. Here he had the good fortune to be admitted to the private laboratory of Magnus, and it was under the guidance of this expert experimentalist that he completed his chemical researches respecting biuret, a derivative of urea. In 1847 he took his degree of *Dr. Phil*, and two years later he published an account of his first electrical researches—into the conducting power of crystals. Other valuable work followed, on the magnetic rotation of the plane of polarisation, on electrical endosmose, and on the coincidence of the conductibility of metals for heat and electricity, the last having been in conjunction with W. Franz. Soon after his marriage with the eldest daughter of the celebrated chemist, Eilhard Mitscherlich, he was appointed (in 1854) to a professorship at the University of Basle, and thence he moved in 1863 to the technical high school at Brunswick, and in 1866 to Karlsruhe. It was in 1871 that he came to the University of Leipsic where he remained until his death. He was first appointed profesor of physical chemistry, but in 1887 he exchanged this professorial chair for the professorship of physics.

Digitized by Google

Among Prof. Wiedemann's researches are those, commenced in 1859 and continued until comparatively recently, on the relations existing between the magnetic and mechanical properties of bodies. Other researches he has published were on the relations between the chemical combinations and magnetic properties of bodies, on electric discharges, and on a determination of the ohm. In 1868 appeared a work by him on galvanism and electromagnetism, in 1871 a second edition of this in three volumes was published and in 1885 the third edition enlarged to five volumes, and with the altered title, "Die Lehre der Elektricität." The latter, besides being a complete theoretical treatment of the subject, contained many new and valuable suggestions. It may also be mentioned that Prof. Wiedemann was a foreign member of the Royal Society.

The death of Gustav Wiedemann will be deplored by scientists of all countries.

REVIEWS.

Distribution de l'Energie par Courants Polyphases. Par J. Rodet. (Paris: Gauthier-Villars.) 1898.

This is a work of some 350 pages; yet, in spite of the fact that many of these are covered with a majestic array of mathematical symbols, we can confidently assert that the interest of the reader need not flag from first to last, so ably and attractively are the subjects of the various chapters dealt with. The mathematical portions—though from the necessities of the case of a somewhat intricate nature—are clear and, as a rule, easily followed; consequently, even should time not permit of their careful study step by step, the meaning of the results obtained can be readily understood. Further, and what is of much greater importance, the results when understood will generally be found to be of real practical interest. In short, the author is one who has had practical experience of polyphase plant, and hence is able to gauge the relative importance of the many considerations involved in its design and working. But too often in technical treatises the writers are led away by their algebra, and after pages of juggling with all the letters of the Greek and English alphabets give us nothing of the slightest real value as a reward for our mental anguish in following their necromancy.

The descriptive and explanatory portions of the book are skilfully interwoven with the more theoretical; and, as we have said, the result is eminently readable. There are seven chapters in all in the work—the first dealing with the history and fundamental principles of the subject, the succeeding four with the generator, the line, the transformer and the motor respectively, the sixth (a very short and, as we think, incomplete one) with meters for polyphase circuits; and, finally, there is a seventh devoted to an interesting decription of the chief polyphase installations yet designed and constructed. It is throughout assumed that the principles of ordinary alternate current working have been previously grasped by the reader, which renders the work at once compact and of moderate bulk. Yet we confess that it seems to us that the laudable desire to keep the treatise within modest limits as regards size has frequently been overdone, with the result of incompleteness in many places. For instance, in the chapter on motors, the very important question of the reaction of the rotor or armature current upon the magnitude and distribution of the field has received but scant consideration; and, again, in the same chapter, it is scarcely sufficient to merely note that there is such a phenomenon as magnetic leakage, whereby a certain portion of the field generated in the stator fails to pass through the rotor, and that this increases with the length of the air-gap and with the load. Considering that the leakage, as M. Rodet himself tells us, amounts to no less than from 10 to 15 per cent. of the total field at full load, we ought at least to be informed of the laws according to which it varies, and of how it can best be guarded against. So also more might profitably be said concerning the leakage of transformers and its effect on the drop of volts, and in the chapter on meters, some mention ought to be made of wattmeters and the methods of measuring the power of polyphase circuits, as wellas of the—perhaps less important—watt-hour or energy meters which are described. Likewise, in many passages, it is a pity that more exact practical details are not given, particularly as the author seems to have had considerable experience with the different types of machine he treats of. To take, at random, an example of this insufficiency, on p. 257, it is annoying to be told that regard must be had for the cooling surface available for the dissipation of the heat generated in the stator. We are aware of that already. What we do want to know is what area of cooling surface per watt wasted has actually been found necessary in practice for a given rise of temperature in one or more types of motor. And such instances might be multiplied. Possibly the author would reply that had he in all cases dealt fully with the matter in hand the work would have become unweildy; yet in the preface he states that he is writing for the good, among others, of those actually employed in the construction of polyphase plant; and it is just such detailed information that the latter require. So also, both from the practical and the theoretical point of view, we think that the question of resonance in polyphase circuits should have been at least briefly dealt with, as with underground mains, where capacity plays a fairly important part, it might under certain conditions happen that a dangerously high voltage would be generated. Yet such faults are common to most technical works, the majority of which possess but a fraction of the merit of the one before us; and it is pleasanter to dwell on the latter's many excellencies.

In the discussion of the line, the effects on the voltage produced by varying the loads on the different circuits of diphase and triphase systems, and the advantage of the star formation with triphase currents provided a fourth wire is employed connecting the centres of the stars, are carefully gone into; while, in the chapter on transformation, the rationale of the Scott system of obtaining a triphase current from a diphase, or a diphase or two simple alternating currents from a triphase, as well as of the various forms of rotary convertor, is considered. In the description of the most important installations given at the end of the work the fact which strikes us most is that, with the single exception of the Dublin line, no British plant is mentioned. Thus once more the humiliating fact that we are lamentably behind our American and continental rivals in this branch of electrical industry is borne in upon us; and yet not only is there a great field for polyphase transmission on a large scale from suitable centres in England itself, but (and this is of greater immediate importance) there is much work for the colonies and abroad now passing, or about to pass, into the hands of others, which our manufacturers might secure for this country would they but rouse themselves into taking more than mere dilettante interest in the subject. F. W.

Industrial Electricity. Translated and adapted from the French of Henry de Graffigny, and edited by A. G. Elliott, B.Sc. (London: Whittaker and Co. 1898.)

This book is the first of a series of volumes upon electromechanics. The present work is said to be introductory to the rest of the series, and while it can hardly be described as elementary, its 149 pages are by no means limited to the broad principles of the law, measurement and application of electricity, but an attempt is made even to discuss details of practical management of plant. Of the twelve chapters the first four of the book deal with the nature, the principles and the measurement of electricity, while the eight last are devoted to its generation and applications. The best written chapter is certainly the first, on the "Nature of Electricity." It forms a short, but more than usually lucid essay on the subject of its title. There are a few references which appear to be slips; thus, on page 45, we read about the "Bellie" meter, when probably the Brillié meter is meant, and (on page 50) Callaud is spelt "Calland." The treatment of the subject of units in the second chapter is, on the whole, clear but rather loosely worded; thus, we read that "electricity is to-day an exact science governed by laws founded on a sound mechanical basis. These laws were formulated by a congress of electricians," and, further on, "These three (the fundamental)

Digitized by Google

units form what is known as the C.G.S. system. . . .' Chapter VI. (on accumulators) is useful, but the next, on "Dynamo Electric Machinery" is comparatively curtailed as a single volume of the series is to be devoted to this subject. There is a fairly obvious mistake on page 100 in the description of parallel and series methods of distribution.

The Electro-Plater's Handbook. By G. E. BONNEY. Third Edition. (London: Whittaker and Co. 1898.)

The chief feature of this—the latest—edition of a deservedly popular work on electro-plating is the revision of the chapter dealing with dynamos for low-pressure electro-plating currents. In this chapter the older machines have been replaced by more recent types. There is also a useful addition to Chapter VIII. dealing with the electro-plating of bicycle and such like fittings, the information on this head now being embodied in two sub-sections dealing respectively with "Nickel-Plating Cycle Fittings" and "Nickelling Small Articles."

THE INDUCTION MOTOR.*

BY ERNEST WILSON.

(Continued from page 731).

Before going further, it might be useful to examine the conditions of a pure rotating magnetic field produced by two or three-phase currents. Let a coil be wound so that the induction for current x may be $x\,(b_1\cos 2\pi\theta + b_3\cos 6\pi\theta + \ldots\ldots)$, and let a series of such coils be wound, n to the period of θ, with equal currents but later in period. In Fig. 3, θ would be represented by the surface between 0 and 8.

$$x = a_1\cos 2\pi t/\mathrm{T} + a_3\cos 6\pi t/\mathrm{T} + \ldots\ldots$$

Next coil $x = a_1\cos 2\pi t/\mathrm{T}\,(t - \mathrm{T}/n) + \ldots\ldots$

Induction $= (a_1\cos 2\pi t/\mathrm{T} + \ldots\ldots)\,(b_1\cos 2\pi\theta + \ldots\ldots) + \{a_1\cos 2\pi/\mathrm{T}\,(t - \mathrm{T}/n) + \ldots\ldots\}\,\{b_1\cos 2\pi\,(\theta - 1/n) + \ldots\ldots\}$.

Work out a simple case first two-phase. Induction in coil $= x\cos 2\pi\theta$. In next coil $= x\cos 2\pi\,(\theta - 1/4)$. Currents are $a\cos 2\pi\,t/\mathrm{T}$ and $a\cos 2\pi\,(t/\mathrm{T} - 1/4)$.

Induction is $= a\,\{\cos 2\pi\theta\cos 2\pi t/\mathrm{T} + \cos 2\pi(\theta - 1/4)\cos 2\pi(t/\mathrm{T} - 1/4)\} = a\,\{\cos 2\pi\theta\cos 2\pi t/\mathrm{T} + \sin 2\pi\theta\,\sin 2\pi t/\mathrm{T}\} = a\cos 2\pi(\theta - t/\mathrm{T})$.

Taking the simple case of three-phase currents we have—Induction in coil $= x\cos 2\pi\theta$; in next coil $= x\cos 2\pi\,(\theta - 1/6)$; in next $= x\cos 2\pi(\theta - 1/3)$. Currents are $a\cos 2\pi t/\mathrm{T}$ and $a\cos 2\pi(t/\mathrm{T} - 1/6)$ and $a\cos 2\pi(t/\mathrm{T} - 1/3)$.

$$\text{Induction} = a\{\cos 2\pi t/\mathrm{T}\cos 2\pi\theta + \cos 2\pi(t/\mathrm{T} - 1/6)\cos 2\pi(\theta - 1/6) + \cos 2\pi(t/\mathrm{T} - 1/3)\cos 2\pi(\theta - 1/3)\} = 3/2\,a\cos 2\pi(t/\mathrm{T} - \theta).$$

In this manner any number of phases may be treated. Now consider a two-phase with the higher periodic terms:—

Induction $= x(a_1\cos 2\pi\theta + a_3\cos 6\pi\theta + \ldots\ldots)$

In next $= x\{a_1\cos 2\pi(\theta - 1/4) + a_3\cos 6\pi(\theta - 1/4) + \ldots\ldots$

In first coil $x = b_1\cos 2\pi t/\mathrm{T} + b_3\cos 6\pi/\mathrm{T} + \ldots\ldots$

In next coil $x = b_1\cos 2\pi(t/\mathrm{T} - 1/4) + b_3\cos 6\pi(t/\mathrm{T} - 1/4) + \ldots\ldots$

$$\text{Induction} = (b_1\cos 2\pi t/\mathrm{T} + b_3\cos 6\pi t/\mathrm{T} + \ldots\ldots)\,(a_1\cos 2\pi\theta + a_3\cos 6\pi\theta + \ldots\ldots) + (b_1\sin 2\pi t/\mathrm{T} - b_3\sin 6\pi t/\mathrm{T} + \ldots\ldots)\,(a_1\sin 2\pi\theta - a_3\sin 6\pi\theta + \ldots\ldots) = a_1 b_1\cos 2\pi(t/\mathrm{T} - \theta) + a_3 b_3\cos 6\pi(t/\mathrm{T} - \theta) + \ldots\ldots + a_3 b_1\cos 2\pi(t/\mathrm{T} + 3\theta) + a_1 b_3\cos 2\pi\,(3\,t/\mathrm{T} + \theta) + \ldots\ldots$$

If any one of a_3, b_3, &c., are not zero, the result will give terms travelling round with different speeds. It is essential to have a simple harmonic current and a simple harmonic field. In this motor a nearer approximation to a pure rotating field might be attained by allowing the coils A and B to overlap. It is evident that, with magnetising coils placed as they are in this motor, a pure rotating field cannot be produced with two-phase currents.

We now to the two-phase current experiments. Each of the coils A B was supplied with alternate currents differing in phase by a quarter period. The results are given in Tables III. and IV.

Table III. refers to the motor when its armature is working on open circuit. The frequency is 53·5, and $\sqrt{\text{mean}^2}$ E_1 and E_2 65 volts. Table IV. refers to the motor when its armature has an extra resistance in each circuit of 0·15 ohm. The frequency is 55, and $\sqrt{\text{mean}^2}$ E_1 and E_2 60 volts. The curves have been integrated, and Fig. 7 shows the important result. The abscissæ represents time in 60ths of a period, the ordinates total induction respecting the surface 2, 3, 4, 5 and 6 in Fig. 3.

Referring to Fig. 3, in which the areas or total inductions due to the two phases are sine functions of *time* and displaced nearly 90deg., we see that if we combine the two-phase curves Nos. I. and II. at different points along $l\,l$, the result is the curve No. III. The curves Nos. I. and II. have areas per half period ($\theta/2$), which, when added together, equal $\sqrt{2}$ of the maximum area of either curve, and the resultant, therefore, represents the maximum induction density experienced, which occurs at positions 1, 3, 5, 7, &c. The induction density over other portions of the surface will be less; curve No. IV. has maximum area and shows maximum density at 2, 4, 6, 8, &c. In Fig. 7 the curve No. I. is the curve $\int \frac{dI_2}{dt} dt$ in Table III.; curve No. 2 is the sum of the inductions given by coils (2 – 3), (3 – 4), (4 – 5), (5 – 6), Table III. when the motor armature is on open circuit. When loaded by inserting 0·15 ohm in each armature circuit, the curves Nos. 3 and 4, Fig. 7, represent the same combinations. We see that the curves Nos. 1 and 3 have the same amplitude and are nearly in phase. This will be seen to have importance in a subsequent part of this Paper.

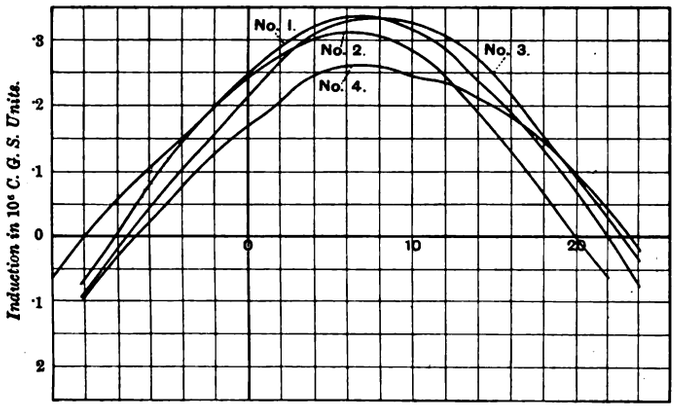

FIG. 7.

Taking the figures as given by the curves in Fig. 7 at the maximum value, and correcting Nos. 1 and 3 for 0·83, the differences between Nos. 1 and 2 on open circuit and Nos. 3 and 4 on closed circuit amount to 23 and 35 per cent. of the greater ordinate in each case. Table III. shows that on open circuit the maxima for the coils (2 – 3), (3 – 4), (4 – 5), (5—6) are 0·130, 0·123, 0·135, and 0·096 in 10^6 C.G.S. units. Table IV. shows that when loaded these maxima are 0·107, 0·102, 0·146, and 0·043; coil (5 – 6) suffering the greatest diminution. On open circuit the phase differences with regard to maximum induction are 48deg. for coils (3 – 4), (4 – 5), and 30deg. for coils (2 – 3), (5 – 6) as against 45deg. with a pure rotating field. On load these phase-differences are 72deg. and 72deg.

(*To be continued.*)

THE CROWDUS STORAGE BATTERY.

A year ago* we described the method of manufacture of the Crowdus storage battery, a cell of American origin. The battery is now being made in this country, a small factory, which we have had the opportunity to inspect, having been equipped by the Crowdus Accumulator Syndicate (Limited), under the direction of Mr. W. A. Crowdus, the inventor, who is now in London. Since our description last year the battery has been modified to some extent, the principal alteration being the abandonment of aluminium as the material for the negative plate. The principle underlying the mode of construction is that the lead grid which holds the active material is made extremely light, there being no advantage in increasing its weight and strength sufficiently to outlive the active portion of the plate. The thickness of lead has, after prolonged experiment, been chosen at 0·037in. Sheet lead of this thickness and of the proper width is passed through an automatic press, driven by an electric motor, and the series of elongated perforation seen in Fig. 1 are cut in it, the strips of material left between the perforations being bent to alternate sides of the plate. This is clearly shown in Fig. 1. The plate is then passed through the cutting machine and cut off to the proper length, after which it is pickled in caustic soda and washed in sulphuric acid previous to being pasted.

The plate in this form is quite light and flimsy, the lead being very thin as already mentioned, and the perforations having diminished the weight of the plate by about 50 per cent. When lifted it is not even strong enough to carry its own weight without bending over. The reason for this has been stated above; the weight of the paste it contains afterwards is twice that of the lead foundation

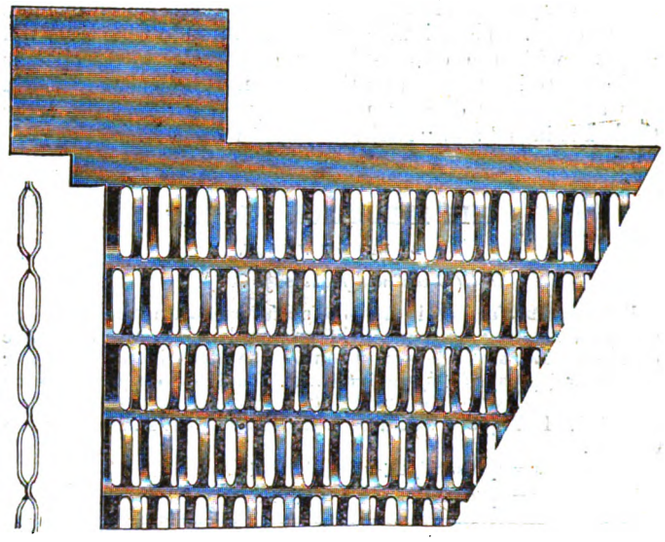

FIG. 1.—Plate before Pasting.

itself. Next, the plates are placed in turn on a rough balance, and the lighter ones chosen for negatives and the heavier for positives; the lightest of all being set aside for the outside positive and negative plates. We say outside positive and negative plates, as an even number, and not an odd number, of plates is employed. The paste—a red lead mixture—is then put in by hand with the help of a rubber spatula, and the plate then presents the appearance shown in Fig. 2. The same paste is used both for positive and negative plates. After a sojourn in the drying room the plates pass a hand-worked machine, which folds up an edge for soldering, and they are then burned together. A thick lug of lead-antimony alloy is used at the top and a solid bridge-piece at bottom, as shown

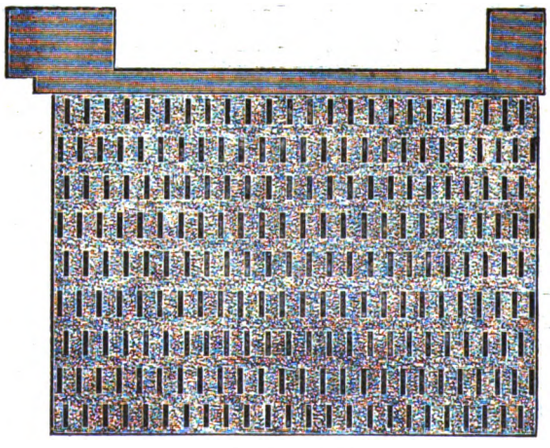

FIG. 2.—Pasted Plate

in Fig. 3, so as to ensure an equal current-density on all parts of the plate. The terminals are made of a sufficiently hard alloy, claimed to be absolutely acid-proof.

The next process is that of forming. This is done in heavy lead dummies, the plates being kept ¼in. from the surface of the dummy plates by ebonite separators. By chemical and electro-chemical processes the positive plate is converted into spongy lead, and then by a modification of the ordinary forming process into peroxide. The forming of the negative plate is by the first part of the process used for the positive. This method of forming was alluded to in greater detail in the description referred to above. The formed negative plates are kept in water until the cell is assembled for sending out.

* *The Electrician*, Vol. XL, p. 682.

Digitized by Google

In assembling the cell, each plate is first wrapped with sheets of cellulose obtained from wood pulp, resembling stiff paper. In addition, a perforated sheet of a pulpy insulating material, resembling bad cardboard or over-thick soft blotting paper, is placed

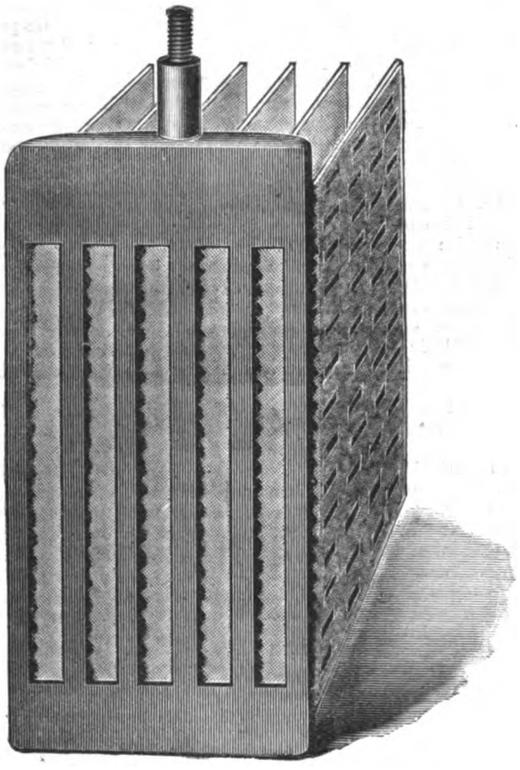

FIG. 3.—Plates ready for Forming.

between the plates. This absorbs most of the liquid in the cell, and in doing so swells, and thus acts as an efficient separator between the plates The boxes are of ebonite with bars at the bottom to keep the plates clear of any material that may have fallen down, and with tightly fitting covers sealed with rubber solution.

ELECTRIC LIGHTING SCHEMES FOR THE CITY OF LONDON.

Sir Courtenay Boyle, K.C.B., opened a Board of Trade inquiry on Monday, at the Guildhall, London, on the applications by the Charing Cross and Strand Electricity Supply Corporation (Limited), the Metropolitan Eiectric Supply Co. (Limited), and the Smithfield Markets Electric Supply Co. (Limited), respectively, for Provisional Orders to supply electricity for public and private purposes within the City of London district.

The following counsel appeared: For the Charing Cross Company, Mr. Shiress Will, Q.C., and the Hon. Sydney Holland; for the Metropolitan Company, Mr. Pope, Q.C., Mr. Fitzgerald, Q.C., and Mr. Moon; for the Smithfield Company, Mr. Balfour Browne, Q.C., and Lord Hugh Cecil; and for the City of London Company, Mr. Cripps, Q.C., Mr. Freeman, Q.C., and Mr. Roskill. Mr. A. J. Walter represented the City Corporation.

I.—The Smithfield Company's Case.

Mr. BALFOUR BROWNE, in opening for this case, said they had struck out of their application power to supply in St. Luke's and Holborn district, as the local authorities there had refused consent. They had now decided to ask the Board of Trade to sanction a Provisional Order for supplying the City of London, and to dispense with the consent of the Corporation, because there were special circumstances which justified them in doing so. The present City of London Company was incorporated in 1891, under three Provisional Orders, which were afterwards amalgamated into one. This Company claimed to have the exclusive right of supply for 21 years, granted them by the Commissioners of Sewers, but he contended that the Commissioners had no power to make such a grant, as the idea of Parliament, in the clause in their Act, was to give the Board of Trade power to sanction two companies in one area. This had been done in the case of the Marylebone Vestry and the Metropolitan Company. The proposed competition had reference to two different sorts of lighting. The Company he represented would give a continuous current supply, which was of real advantage for private lighting. That system was much better than the alternating system of supply by the City Company, which he was instructed had now gone to America for machinery for providing a continuous current supply. Without competition the price of lighting in the City would necessarily be high. The capital of the City Company was £1,200,000, and it had succeeded very well under the shelter of its monopoly. He was not going to make complaints, but he took the line that the Board of Trade would come to the conclusion that competition was a good thing. The Smithfield Company was incorporated in 1897, with a capital of £100,000 and £50,000 four per cent. debentures. The primary object of the Company was to supply light to the Corporation markets under a concession from the Corporation. The business of the Smithfield Company had been carried on without a Provisional Order, but they were prepared to place themselves under the Board of Trade, having, in fact, all along carried on their business on those lines. The Company was already in the City, and there were strong objections to big companies covering large areas because they put their generating stations outside the districts,

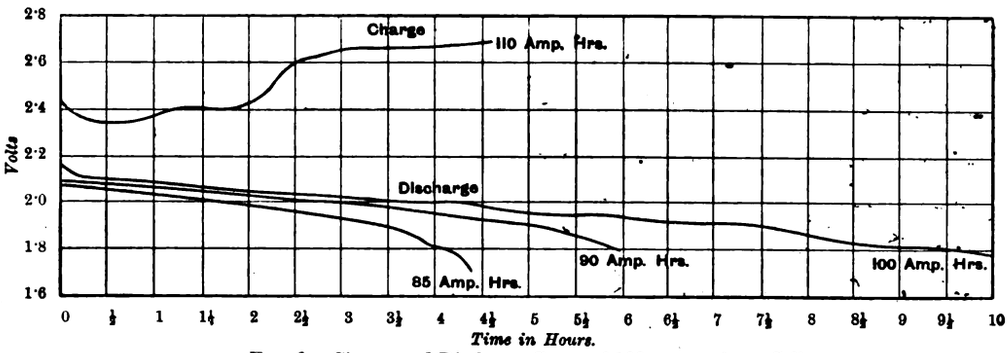

FIG. 4.—Charge and Discharge Curve of 100-ampere-hour Cell.

The following dimensions and data are of interest. They refer to the 100-ampere-hour 12-plate cell:—

Dimensions of box	5⅛in. × 3⅞in. × 8⅛in.
Total weight	14lbs.
Height over all	9⅛in.
Active surface of each plate	6⅛in. × 4⅝in.
Internal resistance	0·008ohms.

Available capacity at	10	amperes	100	ampere hours.
"	"	15	"	90 "
"	"	20	"	85 "

Results of tests on a 100-ampere-hour cell—4½ hour charge and 4½ hour discharge.

Watt-hour efficiency	51·9 per cent.
Ampere-hour efficiency	76·9 "
Current density	0·064 ampere hours per square inch
Ampere hours per lb.	5·98
Watt-hours per lb.	11·0

Fig. 4 is a typical charge and discharge curve of one of these cells. It will be noticed that 50 per cent. of the discharge is at over 2 volts. We should mention that the Crowdus cell is designed essentially for traction and not for central station work.

and so evaded the obligations they were under to sell the whole of their plant and generating stations to the local authority. The Smithfield Company would have a site inside the City, while the Metropolitan Company had their station at Willesden. He also referred to the Charing Cross and Strand Co., which even now was competing with the Metropolitan Company. The threat of competition had already led the City of London Co. to reduce their charges, and he urged finally that of the three companies his was in the best position to compete with the existing company.

Mr. V. B. D. COOPER, consulting engineer to the Smithfield Company, stated that the Company at present supplied electric light for the avenues of Smithfield Market free of charge to the Corporation. Their system was the continuous current, which was the best system where power was required. There was a large opening for that system in the City, and a large demand would arise if the Provisional Order they asked for was granted. The Company was in a position to commence operations at an early date. The City of London Company had, up to the time of these applications, been charging 7d. per unit, and had now reduced it to 6d. That Company's system, except for the street lamps, was alternating current. There were 90 insurances offices who had signed the petition in the Smithfield Company's favour. They had sufficient land to make a large extension of their premises in Charterhouse-street, and could begin supply as soon as their mains were laid, while the other companies would have a great deal of work to do. They had offered to supply at 5d. per unit for

Digitized by Google

light as a maximum, with discounts, and for power at 2¾d. per unit. This was with a view of having their plant in operation all day, and to induce printing works to take current for power, which they supplied at present at 2½d. per unit for power purposes. They could pass by the railway line to Blackfriars. To supply the City the Company would require an additional acre of land for a generating station to increase their supply by 15,000 H.P. The Corporation were not the lighting authorities of the City when the contract with their Company was drawn up. The Commissioners of Sewers held that position. He was not aware that the Corporation had refused to recognise the Smithfield Company, the contract being with two gentlemen who were the only persons recognised by the Corporation. They were liable to be removed at six months' notice. The site adjoining their premises was originally reserved for cold storage. His Company had not yet paid a dividend. The City of London Company had made a suggestion to compete with them at Smithfield.

Mr. SCHENCK, one of the Directors of the Smithfield Company, said they would require additional plant and capital to enable them to supply the City. There would be no difficulty in raising the necessary capital. Their present capital was about £110,000, and the capital was subscribed by the public twice over at par.

II.—The Charing Cross and Strand Corporation's Case.

Mr. SHIRESS WILL opened the case for the Charing Cross Company. That company, he said, had a capital of £150,000 in debentures, £100,000 4½ per cent. preference shares; and £250,000 in 5 per cent. ordinary shares. They had issued £70,000 debentures at 5 per cent., and they had borrowed on the rest £80,000 at 4 per cent. The preference shares, first issue, were subscribed four times over, and the second issue at a premium of 20 per cent., and £150,000 ordinary shares had been subscribed. They had 104 miles of mains, and among their consumers were several Government offices, all the large hotels within their area, and 20 theatres. If they had not done their duty there would have been plenty of evidence against them. Their petition was signed by upwards of 5,000 persons, including a large number of newspapers and printers, and the great bulk of the trading community. The petition maintained that a monopoly was adverse to the interests of the public. In one portion of St. Martin's there were three electric lighting companies, but he was not afraid of competition. There was an enormous demand for electric lighting in the City, and there was room for more than one company. Their average price for current was 4·36d., as against 6·22d. of the City of London Company. All they asked for was the power to compete.

Mr. E. WILMOT SEALE (secretary of the Charing Cross Company) said their financial position was one of the best in London. They supplied the London County Council, nearly all the hotels in Northumberland-avenue, 23 theatres and other important places, also a number of leading newspapers and others with motor supply at low tension. Their pressure was the most even in London, and the less pressure over the proper pressure of 100 volts produced an even and less costly light to the consumers. They went to the Corporation in 1897. It had been suggested that they should purchase the City Company for £3,000,000, and that led to a correspondence which, however, came to nothing. They were prepared to supply the City customers at from 5d. to 4d. per unit, and motive power at 3d. to 2d. The Metropolitan Company were purchasing current from other companies, and he submitted that that was contrary to their Order. That company's nearest station was in Sardinia-street, which had been scheduled by the London County Council. At present they had a station at Lambeth and two others in contemplation. The Charing Cross Co. purchased the plant from Messrs. Gatti for £70,000. The Company had the order before they bought the plant. They were always in favour of competition, and had been and were now actively competing with the Metropolitan Company. They supplied 1½ miles in Holborn and had mains in St. Giles. The supply was partly brought from Lambeth and partly from Maiden-lane (Strand). They had a distributing station with a large output nearly ready to start. There was nothing in their Provisional Order to prevent their laying mains outside their area of supply.

By Mr. MOON: Have you the right to break up streets in all parts of London?—We break up streets by agreement with the local authorities and the consent of the London County Council. We have also the consent of the Duchy of Cornwall, the freeholder in part of Lambeth. We get across the Thames by consent of the London County Council.

If you obtain your new site anyone under the nuisance clause can bring actions against you?—No, the plant has been perfected, and there will be no vibration or other nuisance. I am not prepared to disclose the site.

Witness continued that the figures previously put in were prepared by Mr. Campbell Swinton, who no doubt would be called if they were questioned. The price, 4·36d., was the price for the whole supply, whether for lighting or motive power.

Well, compare that with the Metropolitan?—I cannot do that, because I do not know what motive power the Metropolitan Co. employs. The Metropolitan have bought from other companies to the extent of £4,000.

Mr. MOON: We do not deny that we have purchased up to the end of last year.

Sir COURTENAY BOYLE: Is that a permanent arrangement?

Mr. MOON: No; last year we only bought to the extent of £500.

By Mr. WALTER: In the event of the Board of Trade holding that the consent of the Corporation be dispensed with, will your Company be willing to submit to a clause giving the Corporation power to purchase the whole undertaking, whether the generating stations be within or without the City?—Yes.

Will your Company give an undertaking to keep the generating and distributing stations for the City separate from the other districts?—Yes, that is until the new generating stations are ready. Until then we should use our present stations.

Sir COURTENAY BOYLE: That is a qualification of the answer.

By Mr. FREEMAN: His Company was in a very favourable position. It supplied large buildings in a small area. It would be the same if they supplied the City. Their average charge was 4·36d. since last year, when it was 4·46d.

Mr. W. H. PATCHELL, chief engineer of the Charing Cross Company, said there had always been active competition with the Metropolitan Company. The Strand district included half-a-dozen parishes. They were now going with the Holborn and St. Giles districts. He produced a chart for the foggy days in March this year, which proved the evenness of the pressure. The difficulties suggested as to the supply for the City could easily be met. Since they had offered to supply the City, the City of London Company had been putting down continuous-current plant for motors. They joined the City boundary, and could readily extend their mains. If they obtained their Provisional Order they would take immediate steps for additional generating stations. There was room for extension at their Lambeth station. Their charge for current was 7d., then 6d., then 5d. and then 4d., but this obviously did not mean that the consumer would get all his current at 4d. per unit. If the lamps burnt for 24 hours the mean price would be 4·4d. The surplus power at Lambeth and Maiden-lane was a reserve for 68,000 lamps. The capacity at their two stations was 210,000 8 c.p. lamps, and 142,000 were actually burning. They had space to make the capacity up to 360,000 by Christmas. That would leave them ample power to supply the City at first.

By Mr. CRIPPS: At what time of the day is your maximum load?—It varies between winter and summer. In the winter it is about 5 o'clock, and in summer about 8.

If you were to supply the City you would have to have a distinct and separate generating station from your present establishment?—Ultimately, certainly.

By Mr. BALFOUR BROWNE: They were earning a dividend of about 8 per cent. Their present district was considerably under a square mile. The price of 4·36d. per unit was calculated to include motive power supply, but that was under 10 per cent. of the total. They would have a good market for such a supply in the City of London.

By Mr. FITZGERALD: They brought their current from Lambeth over Waterloo Bridge and the South-Eastern Railway bridge. It would be a little over a mile farther to come into the City. They, of course, would have to lay further mains.

By Sir COURTENAY BOYLE: Allowing for the growth of St. Giles's and Holborn, will not your margin of 68,000 lamps be eaten up very rapidly?—At last year's rate it would be about 28,000 for this year. But we are laying down further plant which would give us about 48,000 8 c.p. lamp capacity.

You contemplate the possibility of acquiring a new generating station. I don't want to know the exact site, but have you any estimate as to the amount of supply it would produce?—We should require 15,000 H.P. for the City, which, allowing for the growth of the City of London Company, would need 300,000 lamps.

Evidence was also given by a number of customers of the City of London Company who complained of bad and irregular service. These witnesses included representatives of Messrs. Smith, Payne and Smiths (bankers); Messrs. Capper, Son and Co. (drapers); Messrs. Hitchcock and Williams (warehousemen); the Sun Fire Office; and the Union Bank.

Mr. BROOKE HITCHING (who admitted he was not representing anybody but himself) said if the Board of Trade gave a competing order to one of these three companies he did not believe that competition would result. The citizens would have their streets and pavements torn up, but would not get their electric light at a lower rate than at present. There was little demand for electric light at night, as there were no theatres in the City, and the public-houses there were almost empty at night. The load was a day load. His opinion was that if two, three or four companies were coming into the City there would be some *sub rosa* agreement to keep the prices at one level and benefit the shareholders to the disadvantage of the ratepayers and consumers. He hoped that the Board of Trade would not recommend any order unless competition could be reasonably assured. He was in favour of the municipalisation of all these undertakings, and then competition would not be necessary.

III.—The Metropolitan Company's Case.

Mr. FITZGERALD (for the Metropolitan Company) said the Company had a share capital of £1,000,000 and powers to issue a similar amount of debentures. They had actually a paid-up share capital of £743,530, and their credit was excellent, their £10 shares standing at £18, so that whatever powers they got they were in a position to execute them. They had five generating stations, and in addition to that they had acquired under their Act of last year a large area at Willesden for a generating station, which was bounded by the Regent's Canal and two railways, so they could get coal on good terms. They were prepared to give a supply on the continuous current system. Their alternate-current supply would be taken to sub-stations and reduced to a continuous current. The boundaries of their district were conterminous with the City at Aldersgate down to the Thames Embankment, and they could supply a large portion of the City in a short time. The main point before the inquiry was whether competition was desired in the City, and, if so, which of the three companies should have the Order. He could not regard the application of the Smithfield Company as serious. Its capital was small, and it was barely paying its way. Its present generating station was wholly unsuited for the purpose, and they could be compelled to give it up at six months' notice from the Corporation. The Charing Cross Company had two stations, but they had an increasing business, and had recently obtained a considerable accession of territory; their margin of supply, therefore, was absurdly small. They talked of a new station, but had not even selected a site for it. As to price, the Metropolitan Company was prepared to take 5d. for light and 3d. for power as a maximum. If the Order was granted to them, the competition would be of a most practical character. The Charing

Digitized by Google

Cross Company had a small, compact and valuable district, while the Metropolitan district extended over a wide area. It was, therefore, not fair to take the average of a small wealthy district against a large, straggling district. In addition to that, the moment they had their Willesden station complete they would be able to generate and distribute more economically than the Charing Cross Company. It had been suggested that there was an alliance between the Metropolitan and the City of London companies. There was nothing of the sort. The position was this. Of the three companies applying, they were the strongest financially, the strongest electrically, and their position at Willesden made it certain that they would be able to supply the City before any of the others could do so.

Mr. E. CUNLIFFE OWEN, secretary of the Metropolitan Company, said that all their stations were coupled up, with the exception of Whitehall, which was quite separate. Competition had been permitted in part of their area. Their buildings at Willesden were practically complete. The demand for their supply had risen rapidly and steadily, so that they had been able to gradually decrease the charge. The first charge was 7¼d. per unit, and at the present time the average was rather under 5·2d. per unit, and they hoped to supply even more economically.

By Mr. SHIRESS WILL: They had no competition in Paddington or Marylebone, and in both those districts the demand would be very great, but it would not exhaust the Willesden station. He was not in favour of competition in Marylebone, where they had an arrangement with the Vestry.

Sir C. BOYLE: You do not object to competition in Marylebone?—No; but we do to rate-aided competition.

Mr. R. R. TODD, resident engineer at the Metropolitan Company's Willesden station, said they could supply the City by the end of the year. When their works were complete their supply would be 27,000 to 30,000 kilowatts. The present generating power was 7,000 to 8,000 kilowatts. The Willesden works would more than double their generating powers, and be quite able to supply the City of London. They would have direct current at high pressure. The pressure would be 10,000 volts, to be converted into continuous current by rotatory transformers.

Mr. J. CECIL BULL, manager and secretary of the City of London Co., said the agreement of his Company with the City was registered in July, 1891. They first paid a dividend in 1895 of 5 per cent., in 1897 10 per cent., and last year 6 per cent. on their ordinary capital. The number of private consumers and the number of 8 c.p. lamps was in 1892, 242 consumers and 11,860 lamps; and in 1898, 7,414 consumers and 355,825 lamps. There had been a continual increase. The number of units sold in 1895 was 2,814,000 at an average price of 7·56d, and in 1898 5,837,317 at 7·22d. Since the starting of the Company a large number of consumers had come on their mains who had previously provided their own supply. They had received very few complaints, but they did get some in December last, and on March 14 they received 38 written complaints. Those came from 10 transforming districts out of 22 or 23. In almost every case the lamps were very old. Nine out of ten of the complaints, with the exception of foggy days, were entirely due to the consumers' own fault. In December last they had a series of mishaps which were practically unavoidable. Pipes necessary for some new boilers were not delivered according to contract, and they had to use bad coal, and the local authorities had harassed them as regards smoke. Their present capital was £800,000 ordinary shares, £400,000 preference shares and £400,000 debentures. They had issued that capital with the exception of £200,000 ordinary shares. They had a large reserve fund. They were bound to provide 7½ per cent. for depreciation, and they had satisfied the Corporation. They objected to competition because of the particular circumstances of the City. The proposed competition was most unjust, because their capital was raised on the faith of their agreement with the Corporation, and the demand for current was practically only during the winter months. Ninety of their customers were tenants of offices, and they had no theatres in the City. The net cost of their supply was about 5d. per unit.

By Mr. FITZGERALD: Is not competition advantageous to consumers?—On the point of price, I suppose it would be.

By Lord HUGH CECIL: His company was not more liable to accident than other companies. They had 502 arc lights. They had paid £196. 7s. 3d. in penalties in 1893 in reference to street lights, but that was a very small matter.

By Mr. POPE: Are your accounts kept strictly according to the Board of Trade rules?—Yes; but the Charing Cross Company's are not. The Corporation inspect our accounts. It required double the outlay in the City to get the same net result as elsewhere. In the West End there was a regular demand which did not exist in the City. He objected to competition on unfair terms. His Company could not poach on other districts, as they were confined to the City.

Mr. FRANK BAILEY, engineer to the City of London Company since 1895, said that up to last winter the supply at full pressure had been given without difficulty. They had had great trouble with their coal supply. The total capacity of their plant was 11,500 kilowatts with 20,000 H.P. They had 66 per cent. of their lamps burning at a time, whereas the demand was only 30 per cent. In consequence of that they required double plant. The number of lamps was 355,825, and the price for public lighting was 2·93d., and for private lighting 6·23d. They had 22 distributing districts, and in no other city, so far as he knew, was there so ample a supply. Competition would not guarantee the consumers from breakdowns. The conditions of the Company in the City were peculiar. They had a sure rise in the curve and heavy loads, but only for a short time. The load rose so rapidly that special plant and handling were required.

Sir COURTENAY BOYLE said it was very important that the Board of Trade should have evidence from the City engineer as to his aspect of the present problem, and some information from the Committee of the Corporation charged with the business as to whether, supposing any Provisional Order were granted, they had or had not any preference for one or other of the competing companies. The Board of Trade were most anxious to consult the views and wishes of the citizens of London.

Mr. WALTER said the matter would doubtless come before the Court of Common Council.

The inquiry was adjourned until April 11.

PARLIAMENTARY INTELLIGENCE.

COUNTY OF LONDON AND BRUSH PROVINCIAL ELECTRIC LIGHTING CO.'S BILL.

The Committee resumed their inquiry into the petitions against this Bill on Friday, Sir W. Coddington again presiding.

Mr. A. J. LAWSON said the Company proposed to carry their mains through Shoreditch to supply districts beyond, the object being economy. He had estimated what it would cost to put up generating stations and to lay cables under the Bill. The cost of the extension in St. Luke's would be £33,000 or £35,000. The total cost of the cables which they would run under Shoreditch would be less than £10,000. The contemplated expenditure would probably approach some £432,000. In the Northern district £53,866 had been spent, and a further £15,000 in Holborn. They had spent £243,212 in Wandsworth, and in Camberwell £45,900. Inclusive of what had been spent in the provinces in connection with other undertakings, the total expenditure of the Company amounted to £562,587. The Company's called-up capital represented £400,000 of Ordinary shares, £200,000 of the £400,000 authorised Preference shares, at 6 per cent.—on which the Company got a substantial premium—and £200,000, out of the authorised £400,000 Four per Cent. Debentures issued at 108. The Company's energies were not confined to the metropolis, and the grand totals given referred to other districts besides London. Nothing had been paid as dividend on the Company's Ordinary shares up to the present. Interest had been paid on other shares and debentures out of profit on sales of investments, the Company doing a financial business as well as that of an electric lighting company. Apart from financial operations, the total amount of profit made last year, after deducting rents and establishment charges, amounted to £17,375. The financial operations had been directed to finding capital for undertakings in the provinces and in London. So far as concerns London, the Company is one for the supply of electricity, and the powers are sought in that capacity alone. Last year the Company supplied 917,000 units of electricity to a population of 830,000. He was aware that Shoreditch alone supplied 885,000 units, but the greater part was for their own use. Shoreditch had recently reduced its price to 5d. per unit for the first two hours, and 2d. afterwards. His Company charged 7d. per unit for the first 1½ hours, and then 3d. Although the possession of a station on the Thames by the Company would enable it to obtain their coals at 1s. 6d. per ton less, the cost of a site on the Thames, even if they could obtain it, would be prohibitive. Land on the Thames was of greater value than land within a mile of the Bank of England. The promoters were also applying for a Provisional Order for Lee (Kent). The proposed increases and the erection of the new generating station at Camberwell were necessary for supplying the Company's present district, without regard to any fresh area that might be served. The objection raised by Guy's Hospital had reference to the construction of a station on a piece of land adjacent to their institution, indeed running up to the wall of the hospital; but there would be practically no nuisance from noise or vibration if the Company placed its works there. In comparing the Company's charges for current with those of local authorities, regard should be had to the fact that such authorities could effect a saving by using existing offices and present servants in connection with the supply of electricity. They could also arrange their accounts as they liked, and, so far as he knew, they did not submit their accounts to audit. For instance, he believed that last year Shoreditch borrowed from the rates £20,000 without paying interest. Neither was their machinery rated, as they took good care that the Company's should be. It had been suggested that the Company should get no powers to lay down mains before obtaining Provisional Orders in respect of the districts they desired to supply, but he thought it preferable to deal with these matters in once instead of making continual applications to Parliament. The Company did not seek any new areas of supply under the present Bill, but only for rights-of-way and sites for extending existing stations and erecting a new one.

By Mr. COLVILLE: If the Bill were rejected, the Company would not be able to enlarge their station at Wandsworth, so as to meet the demands which would in the future be made for electricity from Camberwell.

Sir. F. BRAMWELL said he had visited the site of the proposed extensions and of the proposed new generating station at Camberwell, and agreed with last witness as to the necessity for, and the capacity of, the sites. They were admirably adapted for the purpose. If the proposed new station was not on the Surrey Canal they would have to go without water and use non-condensing engines. The number of generating stations should be as few as possible. The area of supply of the County of London Company was 25 square miles. There would be no danger of electrolysis to the mains of the Chelsea Water Company. As to the question of breaking up the streets, that was a bugbear which it was not worth while talking about. Depend upon it the local authorities would rate them very heavily when they had the power.

Mr. VIGERS, surveyor, said every description of loss incurred by anyone whose premises were taken would be met by compensation.

Mr. LAWSON, recalled, said the £35,000 he had mentioned would be for the cost of extending the buildings along the canal, but not for laying the mains. The total expense under the Bill would be some £260,000. When

Digitized by Google

the Company offered lately £200,000 Four and a-Half per Cent. Debenture stock to the public it was subscribed some 8½ times over, which showed that the Company was not, as had been suggested, an impecunious one.

This concluded the promoters' case.

Mr. LITTLER, Q.C. (for the Whitechapel Board of Works), said the Bill would inflict upon the petitioners considerable burden and responsibility, as their streets were honeycombed with underground mains, sewers, wires, &c., and were largely covered with wood pavement, which could not be interfered with without loss to the road authority. If the promoters were once allowed to pass through Whitechapel they might, in some future session, do something in the way of competition with the Board of Works, who were themselves supplying electricity. He held that there was some *arrière pense* behind the Bill—that the promoters contemplated something which the Committee knew nothing about. He submitted that the proper course for the Company to adopt would be to go to some site on the banks of the Thames, where there was no population, and where land was comparatively cheap.

Mr. H. HECKFORD, surveyor to the Vestry of St. Luke, Middlesex, declined to reply to Mr. Pember (for the promoters) as to what effect the extension would have on the district.

Mr. G. W PRESTON, clerk to the Vestry, said the effect of the proposed works would be to deprive them of rates to the amount of £1,227. The Vestry lost nothing in the matter of rates in connection with the present generating works of the Company. When the proposed works were constructed, if the buildings were similar to those already in existence the Vestry would no doubt benefit, but there was no guarantee that they would be similar. He saw no reason why in the present case the Company should not pay rates during construction.

Mr. CASTLE, Q.C. (for the St. Luke's Vestry), said that before the Electrical Energy Committee, Mr. Pember, Q.C., in examining the engineer to an electric lighting company, had got the witness to admit that an electrical company coming to Parliament for powers to acquire property should not be distinguished from a railway company coming for powers to take land for a new station. If that held good the parish would be protected against loss of rates. In the case of the Brompton and Piccadilly Railway a generating station was included, and the Vestry in whose district it was were allowed rates during construction.

Mr. PEMBER said that in the Brompton case the clause was put in in respect of the parish where the railway was, but not in respect of the parish where the generating station was.

The CHAIRMAN said that to his mind the difference was this—that in the case of a railway station three or four years were occupied in construction, but that was not to happen in connection with the two undertakings which the Committee had already had before them, and in which they had decided against the contention of Mr. Castle. The value of the property in the district of the Vestry would be almost doubled when the proposed works were constructed, so that the Vestry would be recouped in the course of three or four years. The ratable value of the property which would be taken was £1,237, whereas that of the existing works was £3,500.

Mr. WHEELER, Q.C. (for the Vestry of St. Matthew, Bethnal Green), submitted that the essence of the report of the Committee of last year, on which Mr. Pember had relied, was that if the Electricity Generating Company could not find a generating station in its own district it might go into another district to find it. Then, as to clause 15, which dealt with accounts. However simple the Bill might be in appearance, this clause alone would justify the strenuous opposition which was offered to it. If the clause, which he called the "pooling" clause, and which was to relieve the Company of the necessity of furnishing separate accounts of each of its undertakings, were passed it would put an end to all existing contracts as to purchase at the end of 42 years. It was said that the clause would modify the Act of 1892. Why it would revolutionise it. To exempt the promoters from liability to keep separate accounts would be to sweep away every bargain they had made in the various areas. And it must be borne in mind that it was only on the terms that they should keep separate accounts, and that the local authority was to have power to buy, that the promoters had been allowed to go into those areas. This clause not only prevented purchase, but also reduction of charge. He opposed the preamble of the Bill *in toto*, and trusted that the Committee would not pass a Bill so vicious and so unprecedented.

Mr. W. F. DEWEY, Vestry Clerk of St. Mary, Islington, said his parish had already spent £200,000 on electric supply, and proposed to spend another £100,000. They supplied electricity for electric lighting at 3½d. per unit, for power during the daytime at 3½d., and for private lighting at 7d. for the first hour and 4d. for every subsequent hour. As an electric lighting authority, they had a strong desire to reserve to themselves the streets down which the promoters were seeking powers to go. One of his great objections to the Bill was that the Bill, as drawn, in the clause dealing with accounts, would render it impossible to acquire the Company's undertaking in Islington. He knew it was said that the Bill did not enable the Company to supply electricity in Islington, but the moment they had laid a main down a street there was nothing to prevent them from spreading wires transversely in order to supply private consumers. He maintained that Islington was not between St. Luke's, where the Company's generating station was situated, and Hackney, which the Company wished to supply with electricity. At present the streets of Islington were congested with electrical mains. The Company were seeking to evade the possibility of Islington purchasing any part of their undertaking which might be in the parish. The powers contained in the Orders already obtained did not apply to this Bill. Under the Bill private consumers might be supplied. On this point his objection would be met by the insertion in the Bill of a clause declaring that electricity should not be supplied to private consumers in the parish of Islington. If the powers sought in the Bill were granted, the Vestry should have the option of dictating the route by which the Company's wires should go. He should not be content to leave the power of deciding the route with the Board of Trade, as then the Company would be able to suggest the route in the first instance.

Mr. BARBER, surveyor to the Vestry, gave evidence as to the crowded state of the streets underground with wires, mains, sewers, &c. The Vestry were about to start a new 1,000 H.P. engine at their generating station. The nearest route from St. Luke's to Hackney would not be by way of Islington.

Mr. PEMBER, Q.C., said the Committee desired to have details as to the districts affected by the Bill. The facts were these:—Battersea had obtained an Electric Lighting Order in 1896, and Fulham in 1897, and no work had been carried out, though it had been commenced, and the same thing applied to Whitechapel, which had obtained its Order in 1892, and Stoke Newington, which had obtained its Order in 1893. Hackney and Poplar had obtained Orders in 1893, but nothing had been done. Lambeth had got an order in 1893, but had transferred it to a company in 1897. Islington and Shoreditch had got Orders in 1893 and 1892 respectively, and were carrying out the work; Bermondsey and Rotherhithe were applying for an Order, and the Company sought to supply them. In the case of Greenwich an Order had been granted to the Company for a part of the district, and the Company were asking for an Order in that district. In the Lee district an Order had been granted to a company to supply a part, and the present promoters were seeking to supply the district. The Bethnal Green Vestry were applying for an Order, and so was the Company; Camberwell was the Company's district, and so was Wandsworth, and St. George the Martyr, and St. Luke's, Midd'esex, and in Lewisham powers were being sought both by the authority and the Company.

The Committee then adjourned.

LEGAL INTELLIGENCE.

W. T. Glover and Co. (Limited) v. William James Glover and Co. (established 1818), Limited.

On Monday, in the Chancery of Lancaster, before Vice-Chancellor Hall, Q.C., a motion was made on behalf of the plaintiffs for an injunction to restrain the defendants from carrying on business as electric cable and wire manufacturers under the name or title of "Glover." Mr. Maberly, for the plaintiffs, said his clients were Messrs. W. T. Glover and Co. (Limited), of Salford, who had carried on business for many years as electric cable manufacturers, and the defendant company had been formed under the name of William James Glover and Co. (established 1818), Limited, whose head office was in Manchester. The prospectus had been issued about a week previous.

The VICE-CHANCELLOR: I see the business is announced as having been established in 1818.

Mr. MABERLY (for plaintiffs) said there was such a business, but it was simply and solely a wire cable business, and had nothing to do with electricity.

Mr. SUTTON (for defendants): We do not admit that.

Mr. MABERLY, continuing, said that since the notice of motion had been given for that day defendants had inserted an advertisement in the Manchester and London papers to the effect that having been challenged by the plaintiffs as to the right of the defendants to use the name of "Glover," no allotment of shares would take place, and the money received on application would be returned forthwith. This, of course, considerably altered the position of affairs.

The VICE-CHANCELLOR asked if they were ready to go on.

Mr. SUTTON: Certainly.

Mr. MABERLY: I am not. Some of the affidavits have only been received this morning.

The VICE-CHANCELLOR said it was not now as urgent as before. Would it be convenient to let it stand now to the trial of the action?

Mr. SUTTON said it had better so stand. They did not wish it to be supposed that they did not intend to fight, and to fight hard, for that was their intention.

The VICE-CHANCELLOR: I quite understand that. The Company is registered, I understand, and is, therefore, in operation, and nothing will be done now to prevent those who have carried on the business carrying it on on the same lines as hitherto.

Mr. SUTTON: There will have to be a new action against W. J. Glover.

Mr. MABERLY: I was going to ask that it be with liberty to me to amend.

The VICE-CHANCELLOR: Yes.

The proceedings were ordered to stand over to the trial.

In re Whitehead; Ex parte Edison and Swan United Electric Light Co. (Limited).

In the London Bankruptcy Court on Monday, before Mr. Justice Wright and Mr. Justice Bigham, the appeal *in re* Whitehead, ex parte the Edison and Swan United Electric Light Co., from the Staffordshire County Court, was heard. Mr. Muir Mackenzie was for the appellant (the debtor), who appealed from a receiving order made against him on the petition of the Edison and Swan Company. He contended that at the time of the act of bankruptcy there was not a sufficient debt due to support the petition. The Act of 1883 provides that no person is entitled to present a petition unless the debt amounts to £50, and Mr. Mackenzie quoted a judgment of Lord Justice Melluish in support of his contention. It appeared that debtor received goods from the Company on sale or return. He had previously dealt with the Manchester Edison Swan Co., who were taken over by the United Company, together with all the arrangements they had made. The debt due from Mr. Whitehead to the former

Digitized by Google

Company at the beginning of 1898 was £92. 10s. 2d. On June 25 the United Company commenced an action for £105. 17s. 7d., which included the £92 and £13. 4s. 5d. for further goods supplied. Debtor resisted the claim, with the exception of £19, which he paid. He returned goods to the amount of £50. 15s. 6d., and was given credit for £69. 16s. 3d., leaving due £35. 18s. 4d. and on Jan. 13, 1899, judgment was given for that amount, with £25. 0s. 7d. costs. But on Jan. 10 debtor executed a deed of assignment for the benefit of his creditors, and the point was that at the time of this act of bankruptcy the debt was only £35 odd, and that the costs of the action did not become due until after judgment. Mr. Reid, Q.C., for the Company, submitted that the costs became part of the original debt. The appeal was ultimately allowed, with costs.

Henwood v. Howell.

At the City of London Court, Mr. E. N. Henwood sought to recover from Mr. T. J. Howell, telephone engineer, £40 and a declaration that he was entitled to a tenth of his receipts in respect of a new telephone. It appeared that defendant wanted to put his patent telephone transmitter on the market, and went to plaintiff for assistance. Plaintiff stated that defendant signed an undertaking to give him 10 per cent. commission on all money raised at once (funds being urgently needed to take out foreign patents) and a tenth share of all future profits. Plaintiff had introduced the defendant to a firm of stockbrokers, who were to have formed a syndicate, and who advanced defendant £300 on account. Defendant had, however, taken the matter elsewhere, and was about to receive 4,000 shares in a company. Plaintiff asked to be paid the balance of commission on money actually received by defendant, and to have assigned to him 400 of these shares. Defendant admitted receiving some money, but said the shares had not been transferred. He denied knowing the full extent of plaintiff's commission note. He admitted plaintiff had assisted him, but he had no right to a tenth of the profits which might accrue. Plaintiff had taken advantage of his blindness! He did not know the nature of the document he signed! Mr. Commissioner Kerr said that was a serious allegation to make, and he could find no ground for it. There must be judgment for plaintiff for £40 and for a tenth of the shares which were about to be acquired by defendant, and costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

NOW READY.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s. *New edition ready May 1, 1899.*

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. *Vol. I.*, 12s. 6d. *Vol. II. ready May 1, 1899.*

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of genera as well as special information bearing upon the whole subject of electrica discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 3d. each, post free.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s. post free; abroad, 6s. 6d. Digest post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

IN THE PRESS.

"THE ELECTRIC ARC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. *Vol. II. ready May 1, 1899.*

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R. Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."—By F. C. Raphael

"The Electrician" Electrical Trades' Directory and Handbook for 1899.—The "Big Blue Book" for 1899 is NOW READY. The Directory Division has been corrected up to Feb. 8, 1899, and all the latest new names, changes of address, &c., will be found included. The Handbook Division has been much extended, many valuable tables having been added. The volume contains, also, the large Sheet Tables of Electricity Supply Stations and Electric Railways and Tramways, finally corrected to Feb. 9, 1899. The price of the Directory and Handbook remains the same—10s., post free 10s. 9d.; abroad, post free, 12s. (United States 13s. 6d).

TENDERS INVITED.

The *Bradford* Corporation invite tenders for the supply of a complete battery and switchboard for their electricity supply station, Bolton-road. Specifications can be obtained at the electricity offices, Town Hall, Bradford, and tenders must be sent in to the town clerk (Mr. George McGuire), by Wednesday, April 12. Further particulars will be found in an advertisement.

As advertised elsewhere, the *West Ham* Council invite tenders for two 1,500 I.H.P. engines, two 800 kilowatt alternators and exciters, or two steam alternators and exciters. Specifications, &c., may be obtained at the borough electrical engineer's office, Abbey Mills, West Ham, on and after the 31st inst. Tenders must be sent to the town clerk (Mr. Fred. E. Hilleary) by 4 p.m. of Tuesday, April 25.

The Electric Light committee of the county borough of *Belfast* invite tenders for the supply and erection of mechanical stokers, economisers, pipe work and condensing plant. Specifications, &c, may be obtained from the city electrical engineer (Mr. Victor A. H. M'Cowen). Further particulars are given in an advertisement, and tenders must be sent in to the town clerk (Sir Samuel Black) by noon of Thursday, April 20.

Digitized by Google

The Corporation of *West Hartlepool* invite offers from firms or companies for "free" wiring of premises in the district. Further particulars are given in an advertisement, and offers must be lodged with the town clerk (Mr. Higson Simpson) by April 15.

The *Bristol* Electrical committee require tenders for high-tension switchboards, instruments, &c. Specifications from the city electrical engineer (Mr. H. Faraday Proctor), and tenders must be in by April 10. See advertisement.

The *Poplar* (London) District Board of Works invite tenders for engine and pump room equipment and all electrical plant except battery; boiler house equipment; battery and battery stands; and public street lighting. Tenders to Mr. Potts by 10 a.m. of April 25.

The *Tynemouth* Corporation invite tenders for boilers, &c., economisers and fittings, ejector-condenser, circulating pumps, tanks and pipework and water cooler, pumps, feed pipes, &c., travelling crane, traction switchboard, lighting switchboard, accumulators, cables, and traction steam dynamo. Tenders to town clerk (Mr. Horatio A. Adamson), by noon of April 15.

The Great Northern Railway Co. (Ireland) invite tenders for cables for feeders, returns, potential lines, &c., 6 motor and 6 trailer cars, overhead construction, and battery and booster. Tenders to secretary (Mr. T. Morrison), by April 20.

The Directors of the Lancashire and Yorkshire Railway invite tenders for stores during the 12 months ending April 30, 1900, including signal and telegraph fittings, signal, telegraph and electric light wires, screws, oil, springs, wire, &c. Tenders to secretary (Mr. C. W. Bayley), Hunt's Bank, Manchester, by 10 a.m. of April 3.

The Electric Light committee of the *Salford* Corporation invite tenders for stores. Tender forms from the borough electrical engineer (Mr. Chas. L. Turner), Walness-road electricity works, Broughton, Salford.

The *Leeds* Corporation invite tenders for the supply and erection of coal elevators and conveyors at the tramways power station, Crown Point. Tenders by noon of April 6.

The *Leeds* Corporation also invite tenders for the electric lighting of the new Dead Meat Market and Abattoir. Tenders by April 8.

The Guardians of the Poor of *Rochdale* Union require tenders for a complete electric light installation at the workhouse buildings and cottage homes. Tenders to Mr. R. A. Leach, clerk, Union Offices, Townhead, Rochdale, by April 12.

The *Aberdeen* Corporation invite tenders for the supply of:—(1) two Babcock-Wilcox boilers, (2) one 180-kilowatt steam dynamo (Belliss or Willans and Robinson engine), with steam and exhaust pipes, and one 75-kilowatt balancing set. Tenders to town clerk by April 5.

The *Peterborough* Corporation invite tenders for the supply and erection of Lancashire boilers and economiser; steam dynamos, balancers and boosters; secondary battery and accessories; switchboard and instruments; piping, tank, condensers and pumps; and insulated cables. Tenders to town clerk by April 20.

The *British Electric Traction Co.* require tenders for the construction of about 2½ miles of tramway permanent way from Dudley to Cradley Heath. Tenders by April 14 to the secretary.

The *Rhyl* District Council invite terms for preparing plans, specifications, &c., for a refuse destructor. Further information from the town surveyor (Mr. Robert Hughes). Terms by April 3.

The *Edinburgh* Corporation invite tenders for installing the electric light at the City Chambers (extension buildings). Tenders to town clerk (Mr. Thomas Hunter, W.S.) by 10th April.

The *Wolverhampton* Lighting Committee invite tenders for supplying and erecting about 110 tons of steel stanchions, girders and decking at electricity works. Tenders to borough engineer by April 8.

TENDERS RECEIVED AND ACCEPTED.

The Ipswich Guardians have accepted the tender of Martin and Newby for electric bell work at the workhouse, for £30. 1s. 6d.

The London School Board has accepted the tender of Messrs. Woods and Co. for wiring Upper Kennington-lane School, at £267.

APPOINTMENTS VACANT AND FILLED.

The Wolverhampton Corporation require a mains superintendent, at a commencing salary of £104 per annum. Applications to borough electrical engineer (Mr. C. E. C. Shawfield) by Tuesday, April 4. See advertisement.

The Manchester Tramways committee have appointed Mr. J. Eades, jun. (deputy manager of the Manchester Carriage and Tramway Co.'s works in Pendleton), manager of the municipal car building and repairing works, at a salary of £200 per annum.

BANKRUPTCIES, LIQUIDATIONS, &c.

The statement of affairs of Easton, Anderson and Goolden (Limited) at Oct. 28, 1898, is issued, which shows gross liabilities, £409,091. 13s. 10d. The secured creditors include the holders of the 4½ per cent. first mortgage debenture stock, amounting to £152,250, and the 6 per cent. second mortgage debenture holders, amounting to £30,600. There is a surplus of £79,795. 18s., which figures as an item on the asset side of the account, against which there are liabilities £182,850, showing a total deficiency of £139,907. 5s. Against this deficiency are a number of items (including patents, patterns and drawings, and a claim against Ernest Terah Hooley), which are marked as "uncertain" in value. The unsecured creditors stand for £59,743. 3s. A meeting of creditors will be held at the Guildhall Tavern, Gresham-street, London, E.C., on Wednesday, April 12, at 11 a.m.. when a summary of the statement of affairs will be submitted by Mr. W. B. Peat, liquidator, 3, Lothbury, London, E.C. Creditors are asked to forward their statements of claim against the Company up to Oct. 28 last, to Mr. Peat.

A meeting of the North-Eastern Telephone Co. (Limited) will be held at 22, Dean-street, Newcastle-on-Tyne, on April 13, to receive an account of the winding-up.

A meeting of the Hope-Jones Electric Organ Co. (Limited) will be held at 8, Fenwick-street, Liverpool, on April 25, to receive an account of the winding-up. The Company's business was acquired by the Electric Organ Co.

A meeting of the Electric Date and Time Stamp Co. (Limited) will be held on April 25, at 2, Moorgate-street-buildings, London, E.C., to receive an account of the winding-up.

At a meeting of Electricity (Limited) on Feb. 17 it was resolved to wind up the company voluntarily, and Mr. P. W. Davis was appointed liquidator. These resolutions were confirmed on the 17th inst.

The first meeting of creditors of Charles and Blackwell, trading as electrical engineers under the style of the Central Electrical Engineering Co., at London and Leicester, was held at the London Bankruptcy Court on Tuesday. No offer was submitted and Mr. Wm. Richards was appointed to administer the estate in bankruptcy, with a committee of inspection. Debtors commenced business in October, 1897, and attribute their bankruptcy to the failure of the flotation of the Steady Arc Lamp Co. (Limited). Liabilities £1,626, and assets £571.

Claims against F. Jones (trading as F. Jones and Co.), electrical engineer, 147, St. John's-hill, and 77, Darin-road, New Wandsworth, London, S.W., must be in by April 11. Mr. A. Mackintosh, O.R., 24, Railway-approach, London Bridge, S.E., is trustee.

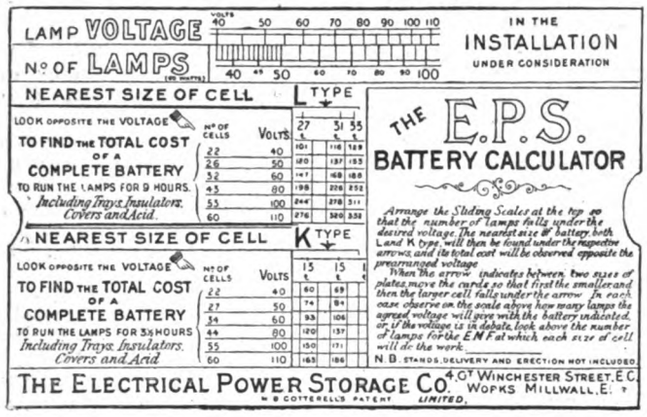
Sale by Tender.—Pursuant to an order of the High Court there is for sale by tender the stock-in-trade, plant, furniture, fixtures, goodwill and British patents owned by the Elieson Lamina Accumulator Co. (Limited). Particulars will be found set out in an advertisement on another page. It will be seen that tenders are to be sent in not later than Wednesday, April 12.

Workmen's Compensation.—At the time when the Workmen's Compensation Act came into operation (July, 1898) we took occasion to complain of the excessive premium rates charged for risks under the Act by the established insurance companies, and prophesied that these companies were likely to seriously damage their businesses in insisting upon such extortionate premiums. We have reason to believe that a good deal of climbing down has been done by the companies, and that this process will have to be considerably extended before large employers of labour will agree to pay the wholly extravagant rates demanded. We are surprised that some well thought out scheme of mutual insurance by large trading concerns has not been arranged. That such a scheme would be highly successful we have no manner of doubt. An example: Messrs. Waring and Gillow (Limited), the well-known decorators and furnishers, were asked by the insurance companies £2,500 per annum as premium under the Workmen's Compensation Act. This sum was considered excessive, and the firm decided to take their own risks. For the first six months, although the number of accidents was greater than in any previous half-year, only £93 had to be paid as compensation, and the firm started the next six months with £2,407 plus interest in hand. For the first nine weeks of 1899 not a single claim has arisen! As was pointed out in one of the leading London papers, recent experience has shown that the insurance companies were wildly wrong in their estimates of risks under this Act. It will be remembered that no sooner was the Act passed than the insurance companies combined to fix the rates, and, instead of giving the Act a chance, and helping to render it popular, and so support the action of Parliament, such excessive rates were fixed as to lead the trading public to the conclusion that the Act was not only unwise but unjust. Such action on the part of the insurance companies leads one to feel that the fixed premiums for other risks are inflated, and so soon as this feeling becomes general it is not unlikely that the "tariff" companies will suffer for their temerity in dealing with risks under the Workmen's Compensation Act.

Digitized by Google

Motor Gun.—It is announced that the 26th Middlesex (Cyclists' Corps) will experiment, at the volunteer manœuvres at Aldershot during Easter, with an electric motor cycle equipped with a service patent Maxim gun. The wheels of the tricycle are fitted with pneumatic tyres and ball bearings, and, should the electric power prove insufficient, an ingenious arrangement provides for four separate safety cycles being coupled together and attached to the pole of the gun carriage. The result of the experiment will be watched with interest, as it is generally considered that a large demand is likely to arise for this class of motor-driven vehicle.

E P S. Cells.—The Electrical Power Storage Co. have forwarded us a copy of the "E. P. S. Battery Calculator," which is a cardboard slide rule of similar character to the well-known Trotte Wiring Slide Rule, and gives a mass of tabulated information concerning E.P.S. batteries which is likely to prove of much service to installation contractors. By means of recesses cut in the two faces of



the card and a sliding tablet, numbers, prices, &c., of L type, K type, Kws type, and Klp type cells is available for different voltages and numbers of lamps. The whole of the information is obtained at a glance, and by means of this calculator a contractor is able to find the total cost of complete battery equipments for any given output and conditions. The illustration (a half-size reduction of the original) shows one side of the calculator, which gives the number of L or K type batteries for certain numbers of lamps at specified voltages.

Messrs. Schuckert and Co.—We have received a large and well-printed volume descriptive of the history, development and present condition of Messrs. Schuckert and Co.'s works. It is illustrated with fine full-page views of the various shops, and gives a good idea of the enormous amount of work that is being executed there. The following figures alone would be convincing:—In the year 1897-98 no less than 4,547 machines were manufactured, representing an aggregate of 72,477 kilowatts, and in addition 441 transformers, aggregating 8,862 kilowatts, 10,788 arc lamps, 120 projectors, 5,088 ammeters and voltmeters, and 8,017 meters, the turnover being 46,500,000 marks. The works cover an area of 88,100 sq. m., 41,500 of which has been built on. In November last 660 officials and 5,329 workmen were employed at the Nuremberg works, and the total number of employés at the Berlin and Nuremberg works together was 7,757.

Fire.—On Wednesday a fire of no serious importance occurred on the works premises of the India Rubber Co. at Silvertown. The local fire brigade succeeded in extinguishing the flames, which will in no way interfere with the company's operations. All sorts of alarming reports were published in London, which we have the authority of the company to state are exaggerated.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from March 22 to March 28, with the ports of destination:—

Australasia—Adelaide, £1,625; Auckland, £379; Freemantle, £272; Hobart, £95; Sydney, £1,322 (including £192 telegraph material); Melbourne, £167; Wellington, £225. *Brazil*—Rio Janeiro, £170 (including £120 telegraph material). *Canada*—Toronto, £92. *Ceylon*—Colombo, £182. *Denmark*—Copenhagen, £53. *France*—Boulogne, £95. *Gibraltar*, £250. *Greece*—Piræus, £71. *Holland*—Amsterdam, £70; Rotterdam, £25 (telegraph material). *Hong-Kong*, £20. *India*—Bombay, £43; Calcutta, £98. *Malta*, £28. *Russia*—St. Petersburg, £128 (telegraph material). *Siam*—Bangkok, £383. ***South Africa***—Cape Town, £73; Durban, £407; East London, £526; Port Elizabeth, £96. *Spain*—Bilbao. £30. *Sweden*—Gothenburg, £105; Stockholm, £209 (telegraph material). *West Indies*—Teneriffe, £162 (telegraph material); Trinidad, £80. Total £7,481, against £16,509 in the corresponding week last year (March 23 to March 29).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Acton.—Hammersmith Vestry have notified the Acton Council that they cannot undertake the supply of electricity in bulk to Acton.

Adelaide (South Australia).—Mr. F. C. Howard, secretary, South Australian Electric Light and Motive Power Co. (Limited), writes under date Feb. 25:—

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of Jan. 13 appears a statement made by Messrs. Lanyon and Sons, agents for the local gas company, and some of its directors, evidently with a desire to damage my company. The gas company has for many years had a monopoly of lighting in this city and its suburbs, and has always paid large dividends, and now, seeing its fat profits endangered by the arrival of an electric company, has strained every nerve to block and damage the said rival.

The gas company's contract is *not* for lighting the whole city, the Corporation having the right to place the gas lamps where they choose, as witness the fact that my company is shortly to provide arc lamps for some miles of the principal streets to replace a large number of gas lamps. The particulars given of this contract are in the main correct, except as to some important omissions. It would be instructive to know how Messrs. Lanyon arrive at the £4,000 loss this company is to make over the contract, and no doubt your readers will smile at the assumption.

The reason so few ratepayers troubled to vote at the poll taken in September last was that everyone knew that the Gas Company would be badly beaten and that the Electric Company would succeed. Messrs. Lanyon state that in 1894 the citizens declined to allow the Corporation to erect electric arcs and supply electricity. How true this is you will be able to gather from the two questions put to the ratepayers on that occasion, viz.: "Are you in favour of having the streets lighted with electricity at present?" and "Are you in favour of continuing the lighting of the streets with gas?" The Gas Company worked hard, spent their money, and on that occasion were successful.

My company has recently been in getting a private Bill through Parliament which gives it very full powers. We have also acquired all the rights of the Corporations of Adelaide and Port Adelaide, to the exclusion of all others, and are receiving a very large support, so you will understand why the Gas Company have been so bitter in their opposition. No doubt you will say this is only history repeating itself.

It is clear that the S.A. Electric Light and Motive Power Co. is alive to its responsibilities, and that here, as elsewhere, electricity supply has come to stay.

Argentina.—According to the *Review of the River Plate* there were in 1895 17 electric lighting stations in Argentina, with 78 dynamos and 37 steam engines. There were 1,257 customers, with 17,122 incandescent and 651 arc lamps connected. The capital amounted to $3,773,500. The number of houses connnected up at the present time (1898) must be very nearly 10,000, and the incandescent lamps in use nearly 100,000. There are 41 telephone companies, with 15,047 kilometres of lines and a capital of $10,918,740. Telegraphs, 40,814 kilometres with 1,237 offices.

The chief lighting official of the city of Buenos Ayres Lighting Department has submitted a scheme for lighting the whole of the city and suburbs by means of 7,000 arc lamps, 3,000 of which would be lighted all night and 4,000 up to midnight. The annual cost of maintenance is estimated at $690,000 gold, and the capital expenditure entailed in the erection at $1,000,000 gold, repayable in 20 years and bearing 6 per cent. interest. The lighting, interest, and amortisation would amount to $780,000 gold per annum (equivalent to $1,560,000 paper), which is about the present price of gas.

Bangor.—Electric lighting matters here are somewhat involved, and the gas interest is endeavouring to make them more so. Owing to counsel's opinion that the signatories to the electric lighting bond were disqualified from sitting on the Council, the guarantors proposed to withdraw the bond. At the last meeting of the Council it was decided (14 members being virtually disenfranchised) that the town clerk should take steps to obtain possession of the document, which the leader of the electric light party declared he held under the advice of counsel. The Lighting committee now recommend the Council to allow the bond to be withdrawn, on condition that it is given up to the town clerk.

Barrow-in-Furness.—The Electric Lighting committee recommend the expenditure of an additional £4,000 for plant at the generating station, sufficient to double the capacity of the works. It is proposed to apply for sanction to borrow £15,000 for extensions, but only £4,000 will be expended immediately. The committee's proposals were adopted by the Council on Tuesday.

Bath.—Electric light mains are to be laid in four additional streets, at an estimated cost of £1,100.

Bury.—An inquiry was held last week into the application of the Council to borrow £20,000 for electric light extension purposes. The applications for current were given as equivalent to 11,561 8 c.p. lamps, the present capacity of the station as only 10,000 8 c.p. lamps, and a constantly increasing demand for current. Extensions were, therefore, absolutely necessary.

Customs Tariff Changes.—The following rates of duty are now levied on electrical goods entering the island of Cuba:—$2·50 per 100 on incandescent electric lamps, mounted or not; $7 50 per 100 kilos on wire covered with insulating material and electric

Digitized by Google

cables, and wire enclosed in iron or lead pipes or armoured; $3 per 100 kilos on electric light carbons.

Electric arc lamps entering Spain will in future be assessed for customs under No. 79 of the Custom tariff.

A duty of 30 per cent. is imposed upon the metal stems of all insulators entering the colony of Victoria, porcelain insulators are admitted free.

Dover.—The receipts of the electric tramways during the past year amounted to £9,000, and the net profit to over £2,000.

Electric Power Distribution in the Black Country.—The Midland Electric Corporation for Power Distribution are making progress with their scheme for the generation and distribution of electricity in South Staffordshire and East Worcestershire. Powers have been acquired for Wednesbury, Bilston, Coseley, Darlaston, Heath Town, Rowley Regis, Sedgley, Short Heath, Tipton, Wednesfield, Willenhall, and Bentley in the district of Walsall. The Oldbury and Kingswinford orders are to be transferred to the company, and the councils of Amblecote, Quarry Bank, and Walsall (rural) have consented to an application which the company are making in the present session. A site for a generating station has been acquired on the West Bromwich side of Tipton, with ample canal and railway facilities for the supply of coal, and from this no main or feeder to the outskirts of the district need exceed eight miles in length. The engineer of the company is Mr. G. L. Addenbrooke. It is proposed to commence by putting down plant equal to 5,000 H P., but the works will admit of easy extensions. The site chosen has an area of 30 acres, and extensions can readily be carried to 40,000 H.P. if required. Before raising capital the company are making an effort to come to terms with the authorities of Dudley, Brierley Hill, West Bromwich, Handsworth, Smethwick, Hales Owen, Lye and Stourbridge. The proposed charges for current are: For lighting, 6d. per unit for the first 100 hours per quarter, and 3d. per unit afterwards, with discounts varying from 5 per cent. to 20 per cent. where the consumption is over 100,000 units per annum. For power, 3d. per unit for the first 78 hours per quarter, and 0·825d. per unit for subsequent hours. The company offer current to local authorities for public lighting at 1·6d. per unit.

Electricity in Mining.—The *Financial News* states that an inventor at the Klondike gold fields, struck with the costliness and slowness of the methods used to thaw the frozen soil, has called electricity in to aid the miner, and by means of an electrical contrivance it is claimed that 24ft. of frozen earth can be thawed in the same time that is taken by the more primitive method to thaw 1ft. It is stated that the invention has been sold to an English syndicate for £7,000. If so, we shall probably hear more about it.

Exhibitions.—Increased space having been placed at the disposal of the promoters of the Brussels Exhibition of Domestic Electric Appliances, the time for sending in applications has been extended to April 10. A reduction of 50 per cent. will be made on the cost of carriage of exhibits on the Belgian State lines.

We are asked by Messrs. Handcock and Dykes to notify that, in order to meet the wishes of several surveyors, it has been decided to include in the International Building Trades Exhibition at the Agricultural Hall, London, N., from April 26 to May 6, a display of plant and materials for electric tramway working, so far as they affect the road surface. The opportunity will be a favourable one for bringing to the notice of surveyors, members of district councils and roads committees the latest appliances in this branch of electrical work.

Glasgow.—Sheriff Berry has fixed April 19 for hearing the dispute between the Postmaster-General and the Glasgow Corporation as to laying underground telephone wires.

Hammersmith (London).—At the Hammersmith electricity station, on Tuesday evening, the inauguration took place of the first extension of the generating station and of the public and private lighting. The company were shown over the new station by the consulting engineer (Mr. A. H. Preece). The extensions consist of the following plant:—A new engine-house, 40ft. by 27ft., with rectifier and pump-room adjoining, designed by Mr. Hugh Mair, the Vestry's surveyor; two engines of 500 H.P., built by Messrs. Robey and Co.; two E.C.C. alternators, one Ferranti main feeder switchboard, one 250 H P. water tube boiler, a 500 H P. Ledward evaporator condenser, and three pumps by Messrs. W. H. Allen, Son and Co.

Imperial Penny Postage.—Postage to Malta has been reduced to one penny.

Keighley.—Negotiations are proceeding between the Gas committee and the Keighley Tramways Co. as to the adoption of electric traction and to the supply of electrical energy by the Corporation, who already possess electric lighting powers.

Light Railways —The following further light railway schemes have been approved by the Board of Trade:—From Trowse (Norfolk) to Beccles (Suffolk); from Cheddleton Junction to Caldon Low and Hulme End; from Grimsby to Saltfleetby, with a branch to Cleethorpes; from Stourbridge to Kinver; from Barking Town to the Beckton Gas Works; and sundry short lines in Northumberland and in the townships of Chirton, North Shields, Tynemouth, Cullercoats, Whitley and Monkseaton.

The adjourned inquiry by the Light Railway Commissioners into the projected Finchley, Hendon and District, the Hampstead, Finchley and Edgware, and the Highgate, Finchley and Wood Green Light Railways was resumed on Tuesday. At the conclusion of the promoters' case, the chairman said that in the circumstances the Commissioners decided that the first two schemes should not be proceeded with.

It is proposed to construct a light (electric) railway between Kelsall and Chester, and application is to be made to the Light Railway Commmissioners in May. The estimated cost of the line, which will be equipped on the overhead trolley system, is put at £40,000.

London County Council.—At Tuesday's meeting the Parliamentary committee reported upon the Central Electric Supply bill, recently passed by a Select committee of Parliament. The power proposed to be given to the company to break up roads, &c., outside the area of supply had an important bearing upon the question of purchase, and the committee considered it one which might perhaps be dealt with as a matter of public legislation by an amendment of the provisions of the Electric Lighting Acts with regard to purchase. It was for the Council to say whether or not the bill should be further opposed in the House of Lords with a view to obtaining some satisfactory arrangement with respect to the purchase of electric light undertakings. It was recommended that a petition be presented to the House of Lords with this object, and the recommendation was approved.

The same committee reported that they had had the London County Tramways bill prepared to enable the Council to use one or more systems of electric traction on all or any of its tramways, and for that purpose to reconstruct the tram lines. The schedule to the bill contained particulars of lands in the parishes of Streatham, Camberwell, Lambeth, and Greenwich, which might be used as sites for generating stations, and which at present belonged to the Council as part of the undertaking of the London Tramways (Limited). It was recommended that the bill be approved, and the recommendation was also agreed to by the Council.

The Highways committee reported that a conference had taken place with representatives of the Lambeth and Wandsworth local authorities as to a proposal that the Council should apply for a licence for the experimental use of mechanical traction on the tramways between Westminster Bridge and Tooting. The consent of both those bodies as the road authorities concerned would doubtless be given. Prof. Kennedy, who had been asked by the Council to advise as to the system of mechanical traction most suitable for London, had proceeded to America to investigate the systems in use, and would probably be able to report within a month or six weeks. A proposal that the Lambeth and Wandsworth authorities be asked to give the required current was approved by the Council.

Lucan-Leixlip (Dublin) Electric Tramway.—A Board of Works inquiry into the engineering details of this line was held on Thursday. For the promoters, it was stated that the gauge would be 3ft. 6in. and the rails would be on a raised platform, the height of the surface of the rail not to exceed a foot above the level of the carriage way. The line would be constructed of steel girder rails, 50lbs. per yard, on transverse sleepers. At road crossings, grooved steel girder rails would be substituted, and would be laid level with the roadway. The total length of the line would be 1⅛ miles. The total cost of construction for the electrical equipment (including poles, cables and motor cars) would be £4,950. The motive power would be supplied by the Dublin and Lucan Co. The feeders would be both under and over ground.

Non-County Boroughs Association and Electrical Matters.—The annual meeting of the Non-County Boroughs Association was held at the Westminster Palace Hotel, London, on Friday last, the Mayor of Southport presiding. In their report for the year, the Executive Council of the Association stated that they had considered the General Power Distributing Co.'s bill, the Lancashire Electric Power bill, the South Lancashire and Cheshire Electricity bill, and the Leicestershire and Warwickshire Electric Supply bill, and considered that the rights of the boroughs were threatened by a new danger. If, for instance, the General Power Distributing Co.'s bill was passed, it would sanction a new policy and create a new danger. It had been the settled policy of Parliament to allow municipalities peaceful possession, to sanction the policy of having only one service—municipal monopoly—in a borough. The passage of these bills would break down that policy. The Council were in perfect harmony with the principle that where boroughs (county or non-county) had with the sanction of Parliament established, or were in the course of establishing, undertakings for the public benefit, and had not failed in the performance of their duties, it was not right or expedient that powers should be granted to companies to compete with such local authorities. The Council further considered that the bills promoted by the National Telephone Co. were, doubtless, objectionable and

Digitized by Google

inimical to the interests of non-county boroughs, and that the powers of the Company should not be extended. They objected to any act being passed which might tend to delay or interfere with the Government undertaking the telephone service of the country. It appeared to the Council to be the duty of non-county boroughs to resist the bills on the general principle of objection to hiring what might be termed national powers to a private company. The report of the Council here outlined was approved.

Newport (Mon.).—Thirty-four additional arc lamps have been erected here, bringing the total to 76.

Perth.—Of the offers received by the Town Council for the electric lighting of the town, Mr. Hawtayne considers that of Edmundson's Electricity Corporation the best, but the Council are recommended to retain their electric lighting powers, and to establish municipal electricity supply.

Private Bill Legislation.—On the motion for the second reading of the Baker-street and Waterloo Railway Bill in the House of Commons on Tuesday, Sir T. G. Fardell said the Paddington Vestry objected to the Bill principally because the promoters contemplated establishing a generating station in the district. They had since offered to withdraw the clauses embodying that proposal, but other objections remained. If the promoters would be content to link Paddington Station with their line, all opposition would be withdrawn. The Bill was read a second time.

Ramsgate.—The Town Council are at last awakening to the importance of electric lighting. The engineer has been instructed to prepare a report on the desirability of establishing electricity supply works or of allowing a company to undertake the work.

St. Mary (Islington) **v. St. Pancras.**—For some time past there has been a deadlock, so far as electric lighting is concerned, in two important thoroughfares in the north-west of London—York-road and Brecknock-road—owing to the clashing of interests of the above-named vestries. It is suggested that the new London Government Bill may prove a favourable opportunity for adjusting the boundaries of the two districts, so as to enable electric light mains to be carried down these two thoroughfares for the supply of current to a large number of consumers.

St. Pancras (London).—The Vestry are increasing the salary of Mr. P. N. Hooper, engineer-in-charge of the King's-road station, from £200 to £220 from May next, with annual increments of £20 up to £300.

Shoreditch (London).—The Vestry have accepted an offer of the County of London Company to pay £100 per annum for permission to lay two electric cables through the parish from the company's generating station for the supply of outside districts.

Smoke Nuisance.—At Bow-street on Monday the Charing Cross and Strand Electricity Supply Corporation (Limited) were summoned under the Public Health (London) Act for disobedience to an order requiring them to abate a smoke nuisance. Mr. H. Avory, who defended, said his clients had put in the best possible furnaces and burnt the best Welsh coal, mixed with coke, to diminish the smoke as far as possible. They were under a statutory obligation to give a supply of electricity, and he submitted that under Sec. 24 of the Act they were entitled to claim exemption from further proceedings. Sir James Vaughan adjourned the summons *sine die*, that the defendants' furnaces might be examined as to their efficiency by an expert to be nominated by the President of the Institution of Civil Engineers. This decision is in striking contrast to that of Mr. Slade in the prosecution of the City of London Co., recorded in our last issue.

Southampton.—The Tramways committee recommend the borrowing of £17,159, Mr. Manville's estimated cost of providing and erecting buildings, plant and feeders for the supply of electrical energy to the proposed electric tramways, extending the electric light mains to Shirley, adding two new boilers to the existing boiler house, and the extension of the mains to the Isolation Hospital, which requires current for about 400 8 c.p. lamps.

State Commercial Agents.—It was announced in Parliament on Monday that Her Majesty's Government contemplate the employment of three new British commercial agents abroad.

Stratton.—The Parish Council have been recommended in public meeting to adopt electric lighting.

Trade with Russia.—The U.S. Consul-General for St. Petersburg has recently sent home an interesting set of suggestions concerning trade with Russia. The report states that the population of the Russian Empire at the present time is 130,000,000, increasing annually by about 2,000,000. The area of the country is about 8,500,000 square miles, or one-sixth of the land of the globe. The country obviously constitutes a world large enough to command the attention of leading manufacturers and exporters, who are seeking markets for their surplus manufactures. Preference is given by Russian merchants to dealing direct with manufacturers rather than through agents in London or Hamburg. Catalogues and circulars intended for Russian merchant houses should be printed either in German or Russian (preferably Russian), should state price of the article offered, largest discount, and terms of payment in Russian values. The surest and best plan for introducing goods into Russia is to send samples by a thoroughly competent representative of the business it is proposed to push. An acquaintance with Russian, German or French, while not absolutely necessary, is of great assistance. During the winter season in Russia there are less than seven hours daylight, while between May and September there is no night. Russia offers a rich field for inventors, and manufacturers should study the markets and methods of doing business. It is pointed out that the number of representatives of American firms who visit Russia annually is rapidly increasing, and a long list of well known trading corporations in the States, including several in the electrical industry, accompanies the report. There is a large field in Russia for the introduction of electric street cars, elevators, electrical apparatus and supplies used in electric light, power and traction work. It is probable that immediately after the Paris exhibition of 1901 the goods exhibited by American firms will be re-shown in St. Petersburg and Moscow with the view of influencing orders for American goods.

Village Lighting.—The Tanfield (Durham) Council have arranged to light their district (including Tantobie, Mountsett, Clough Dene, Hobson and Tanfield Lea) electrically. Lighting is to be effected by incandescents, and it is estimated that a substantial saving will be effected in the annual cost.

Weston-super-Mare.—Major P. Cardew held an inquiry on Tuesday into the application of the Weston-super-Mare and District Electric Lighting and Power Syndicate for a provisional order, and into the proposal of the District Council to transfer their order to the Municipal Electric Power and Distribution Company. For the syndicate it was contended that the Council had forfeited their right to transfer their powers. Mr. F. E. Gripper, electrical engineer to the syndicate and managing director to Edmundson's Electricity Corporation, said he had made a rough estimate of the cost of carrying out an electric lighting scheme for Weston-super-Mare, and he thought £15,000 would be necessary to establish works sufficient to supply the compulsory area. He had recommended that £25,000 should be expended in laying mains during the first year, and a further sum of £10,000 for extensions during the succeeding two years. His company originally made offers to the Council, prior to the syndicate, but were informed that the Council intended to carry out the work themselves. The town clerk (Mr. Sidney C. Smith) stated that the terms offered by the Municipal Distribution Company had been accepted by the Council after due discussion. Mr. Offer, of the Municipal Company, repudiated an insinuation of having in any way used undue influence upon members of the Council. Mr. W. C. C. Hawtayne, consulting engineer to the Council, compared the terms submitted by the contending companies, giving preference to those offered by the Municipal Company. At the conclusion of the evidence, Major Cardew said he would report to the Board of Trade at an early date.

Windsor.—The public electric lighting was inaugurated on Saturday evening. Ten 2,000 c.p. arcs and eight 500 c.p. lamps have been erected. Some streets are to be illuminated by means of 16 c.p. incandescents. The Company's tender for the public lighting was only accepted about three weeks ago, in consequence of the Gas Company's proposal to make an increased charge of 12s. 6d. per lamp.

Woking.—By the casting vote of the chairman, the District Council last week decided not to purchase the undertaking of the local electric supply company.

COMPANIES' MEETINGS AND REPORTS.

Willans and Robinson (Limited).

The ordinary general meeting of Willans and Robinson (Limited) was held on Wednesday, at the Cannon-street Hotel, under the presidency of Mr. MARK ROBINSON.

The SECRETARY (Mr. C. S. Essex) having read the advertisement convening the meeting,

The CHAIRMAN said: Gentlemen, the last time I had the pleasure of addressing you, I think, I began by congratulating you on the fact that I had next to nothing to say, and that we had nothing to recommend but a dividend. In rising this time to move the adoption of the report and accounts, I have a different tale to tell, for though the dividend we recommend is happily larger than ever before, I fear you must this time listen to a long speech, for our recommendations are extensive. Growing prosperity has brought upon us necessities which six months ago we could only foreshadow to you, and which we then hoped to postpone somewhat longer. I allude, of course, to the extensions we propose to carry out, and to the additional capital they necessitate. It is a large subject, deserving full explanation by the Directors, and full consideration by us all, and I propose to defer it for a few minutes, so that we may deal first with those matters which really arise out of the half-year's accounts. First, let us congratulate ourselves upon a successful half-year, and the more so as its success is due to reasons which seem

Digitized by Google

to promise even better results for the future. The half-year's net profit has risen from £17,521 to £22,628, an increase of over £5,000. As the paid-up capital increased during the half-year, more interest would be payable, even at the old rate, but even with this correction our real disposable increase in comparison with the preceding half-year, is over £4,000. Profit has increased much faster than capital, which is a true test of success, and one to which I would specially direct your attention. It may be objected that we are now reaping the benefit of capital subscribed in previous years, but this is only partially true; at any rate the improvement in profits has been for several half-years continuous, and not only continuous, but progressive. I think we may fairly attribute it to the success of our plans for increasing the output and diminishing the cost of production; in fact, we are entitled to claim that the advice we gave you four years ago, to sanction new works and a large increase of capital, has been justified by the results. As you know, we shall this afternoon again ask your sanction for a similar step, for reasons identical with those which gained your approval then, and with results which, we believe, will be as satisfactory. Turning now to the report, you will notice in paragraph 2 that the sum applied to depreciation is less than last time, viz., £5,013, against £5,591, which may look like retrogression in our accustomed methods of prudence. This change is due, however, to an alteration in accounts, by which we shall in future deal with the replacing of certain very perishable articles otherwise than through the depreciation account. There is in reality an increase in the total sum thus applied, as might naturally be expected, and not a diminution. Next, with regard to the dividend. When Directors propose a higher dividend than before, with plenty of reason to show for it, I believe they are expected to carry themselves as those assured of the praise of all men. But we know better, because we have taken this rash step before, and remember what happened then, when, after long consideration, and much carrying to reserve, we raised our modest 7 per cent. to 8. The great body of the shareholders undoubtedly approved, but at least one shareholder, of deservedly great weight in our counsels, thought we were rash, and said so. We think the result shows that we were not, and in the proposal we now make, viz., to pay 10 per cent. on the Ordinary shares, while carrying to the reserves, as you will observe, at the rate of no less than £11,000 per annum, we believe that we hold only a fair balance between the interests of the present shareholders and those of their successors. You will readily believe, gentlemen, without our assurances, that your Directors have no wish to face the unpleasantness of a reduced dividend in the future, and if we recommend 10 per cent. it is because we hope to keep it up. Assuming that this increase of dividend receives your sanction, we have a balance left which we propose to apply as set forth in the report. You will notice that we carry an increased sum to the reserve fund. It is but two years since we congratulated ourselves on carrying £3,000 in all to the debenture redemption fund and to the reserve fund combined. This time, for the same two objects, we jointly reserve £5,500, nearly twice as much, and we make still another reserve of £1,265 by increasing the sum carried forward; in fact, the profits reserved this half-year would be by themselves sufficient to pay an additional dividend on the Ordinary shares, at the rate of over 9 per cent. per annum. Further justification for a 10 per cent. dividend can scarcely be asked for. The paragraph showing the appropriation of the balance of the share premiums account will meet, we hope, with your approval. We have carefully considered the valuation of our Thames Ditton property and plant, and, in accordance with views expressed from the chair at former meetings, and received by the shareholders with approval, we have written it down sufficiently to discount any probable chance of a serious loss in disposing of the Ditton property, should we decide later (as no doubt we shall) to remove the whole of the plant to Rugby. We have paid all the expenses of our move, and we have still kept a little in hand for clearing up old matters which remain unsettled in connection with it. And finally we have added £5,000 to our already handsome reserve fund. The growth of the reserve fund, briefly mentioned in the report, gives us all, we think, solid ground for congratulation, and the fact that we have completed five years of existence gives us also some excuse for talking about it; it is the end of a quinquennial period, as the insurance offices say. It is a period we may be proud of. At the end of our first year's work, our paid-up share capital stood at just under £200,000, and our profit for the first year at a little over £14,000. At the end of the fifth year's work, the paid-up share capital stands at £300,000, and the profit for the year a little over £40,000. In the interval we have nearly doubled the capital, if we include the debenture capital, but we have nearly trebled the profit. In the prospectus we talked of earning not less than 12 per cent., available for dividend or reserve, upon £112,500 of ordinary capital; in our fifth year we have actually earned, though of course we have not wholly distributed, about 16½ per cent. upon £150,000 of ordinary capital. The horse-power ordered from us in our fifth year is more than double that ordered in our first year, These figures show not only great advance, but progressive advance; the increased amount of capital we have put into the business has justified itself, by improving the returns upon what was there before. It is with the conviction that the same result may reasonably be expected to follow, that we now ask your sanction to a further increase. That we may not have to trouble you again in the same way, we propose to raise the authorised share capital at once from £300,000 to £500,000, but we do not contemplate issuing at present more than £100,000. It would be idle to say that we look upon our business as anything but a highly progressive one, and in fact we believe that, under the conditions of trade which are now arising, advance is not only safe, but necessary; that for us, standing still means going back. Therefore, we do not pretend to any strong hope that we can stop at £100,000 for more than a couple of years or so, but you may rely upon our stopping there as long as we possibly can. It is difficult to give expression to views which, I can assure you, have been most thoroughly thought out and discussed, which shall be at once full enough to do justice to the arguments in support of them, and yet not so full as to put information unduly at the disposal of rivals. Very briefly, then, the position is this. We believe the electrical industry, whether in municipal hands or others, is about to make great advances. Much more horse-power will be wanted, and much larger engines. In past forecasts of the plant and space we should be likely to require in the future, we have been sometimes charged with rashness, but, in fact, we have been too timid, and as the size of the engines required for driving dynamos has increased, we have sometimes been found unprepared, and the first orders for the larger sizes have gone elsewhere. Happily we have been able to divert the new stream of business, or a sufficient part of it, back to our own shops, when, later, we have qualified ourselves to receive it. But we may not be so fortunate if we again neglect the signs of the times, while I am bound to say that even if the probabilities of very large work coming our way were much less than they are, it would still answer our purpose to enlarge our shops and put down heavier tools, if only for the excellent position it would put us in for taking orders for early delivery. As regards the foundry, that was knowingly built far below our expected requirements, and so we desire it to remain even after doubling it, for castings, at least of some classes, are easily obtained from other foundries. The main feature of our proposals, however, is that we propose to extend the machine shop chiefly by moving the boiler work altogether from Rugby, at some saving, of course, in the extensions at Rugby, but at the cost of building new works elsewhere. An excellent site has been secured near Chester on a 99 years' lease, at a satisfactory rental. It abuts on one side upon the North-Western Railway, and upon the lower part of the river Dee on the other, so that we shall be able to bring moderate-sized coasters, both sailing and steam, alongside our own wharf. A colliery siding connects with our own. We have secured 30 acres, so as to have plenty of room for storage, and for extensions. Of the advantages of the site, for the particular class of work intended, we think there will be little doubt, but perhaps some shareholders are surprised that we are willing to have our boiler works so far from Rugby. The explanation is that the two classes of work are very different, and, further, that the boiler works will require little or no commercial staff upon the spot, the commercial business of boiler selling, and its account keeping, being easily conducted at Rugby. The constructive staff will be wholly separate from that required for the engine business, and complete separation will be a gain to both, while we are confident that only a moderate amount of the Directors' time will be required at Chester. From the point of view of administration, we distinctly prefer a complete separation, and although the distance in miles is a good deal, that in time, between two principal stations on the same railway, is not excessive. It is also worth remembering that some day we may be glad to do some of the engine foundry work at the northern works, which has communication with Rugby by canal as well as by rail. Probably the crucial question you will desire to put is, why have we thus come to the conclusion that a business we intended to work as a mere adjunct to the engine business at Rugby, and which, in fact, we have practically not worked at all, is now worthy of works of its own, and of a large investment of capital? What has changed in the position? Gentlemen, the slow progress we have made in developing the Niclausse boiler business has been frequently commented upon, and none of us have liked it. Let me tell you the reasons, and since I have been largely responsible for the delay, allow me to state them as for myself, though I am sure my colleagues agree with me. The water-tube boiler of the various French types is essentially foreign in details, and though we took long to consider the design before adopting it, and put it through many tests, we never doubted that long, practical use in this country would show the need of changes of some kind. That, in our opinion, has happened. The design is all we thought it, and we believe there is no boiler in the world so good, but we wish to meet English views, or even English prejudices if you will, to modify some points of construction—not of design. It is not desirable to enumerate them, but the methods we wish to substitute are such as can only be carried out upon a large scale. That was not the case in the original construction of the boiler, which appealed to us as involving no speciality beyond high-class machine work, which we were just the people to undertake, while a comparatively few boilers could be made to nearly as good purpose as a great many. We had, therefore, to face this position: We have to make certain changes in the methods of manufacture, which in a sense disqualify the boiler from being made upon the scale, and by the means which we first contemplated; we cannot even begin small, as we always intended. At the same time, by excellent luck, we can find other uses for the Rugby boiler shop, with only small loss in shifting, or even in selling, the special boiler tools we have so far laid down. Shall we abandon the Niclausse boiler, and write off the not very serious amount of capital we have locked up in it? That was the question before us. But while our views about the construction of the boiler had developed, so also had the public demand for water-tube boilers, and so also had our views about the value of the Niclausse boiler. We had begun by believing it at least good enough to make upon the small scale; now we are confident that it is good enough to make upon the largest scale, and that a corresponding demand for it exists, and further that it promises to add to our business an even more profitable branch than we supposed at first. These, gentlemen, are in outline the reasons which have led us to propose to use the present boiler shop as an additional machine shop, and to start new boiler shops elsewhere, and so leave the Rugby site in its entirety for the growth of our engine business. Assuming that we have your approval so far, let me pass now to the mode of issue of the £100,000 of capital which we consider sufficient for the present. We propose to offer all the new shares *pro rata* to the existing shareholders, at the rate of one for every three of the same kind they now hold, and to issue half as Preference, and half as Ordinary shares. As you know, this requires a special sanction by the Preference shareholders, whose separate meeting is to follow this one, at four

Digitized by Google

o'clock. We trust they will remember the rule that the better is the position of the Ordinary shares (and we aim by this scheme at improving that position) the greater is the value of the Preference shares. There will be more of them, but, if our hopes are well founded, they will each be worth more money. We propose to issue at the same moderate premiums as last time the £5 Preference shares at £6 and the £5 Ordinary shares at £7, and to let the shareholders have the benefit of the low rate of issue. Additional applications will also be invited, as usual, for such shares as may not be taken up by those to whom they are allotted. A question which has always come up in our issues has been whether payments should be made promptly or over a long period. Naturally, the Company does not want the money quickly, and, as we ask you to leave the matter in our hands, I may say that we incline to a long period, asking for the first £1 and the premium upon acceptance of allotment—£2, say, in October this year, and £2, say, in April next year. If our scheme is approved the Company will receive £30,000 in premiums, which we propose to dispose of on the same lines as before, first paying from them the cost of removing the remaining tools from Ditton to Rugby, should that course be decided upon, and the cost of moving the boiler tools from Rugby to the Northern site, then writing down any assets which may seem to require special treatment—as to which we suggest writing off "Patents" altogether, and not allowing that heading to arise again as an asset, unless under very special circumstances. These services might together absorb about one-fourth of the amount, leaving a very substantial sum to go to the reserve fund, which we might then hope soon to see in the neighbourhood of £60,000. The question does not arise directly now, but we ought, after this, to address our efforts to so increasing the reserve fund, that when we have the option of paying off the whole of the debenture debt (£100,000) in 1906, we may be ready to do so, and still leave the reserve fund larger than the goodwill. In fact, all this will come about, and more, if we but keep up our present rate of putting by. It is unnecessary to point out what a splendid position we should then find ourselves in, and the dream, after all, appears to be a very probable one. Next, permit me to refer to a personal matter in regard to increases of capital. Those shareholders who have studied the articles of association of the Company will be aware that those there called "the original Directors" (whose share in the management differs from that of our more recent colleagues; in fact, they might be fairly described by the words "managing Directors") receive salaries which increase with the capital of the Company. Roughly speaking, it is not an unfair arrangement, for a big concern takes more managing, and involves more real responsibility, than a small one. But we think there should be a limit to it, and it is right you should know that the "original Directors" have executed supplementary agreements with the Company to the effect that no increase of capital, subsequent to the £100,000 now proposed to be issued, shall carry with it any increase in their salaries, notwithstanding the rights conferred upon them by the articles of association. I have detained you so long, and there is so much to get through, that I refrain from commenting upon the items of the accounts, though pleased, of course, to answer questions. Several of the items of expenditure, which often provoke comment, are lower than usual, but probably such reductions, like the increases which preceded them, and may follow them, are accidental. With a growing business such items tend generally upwards, in spite of all watchfulness. I now move the adoption of the report and accounts

Mr. H. PERCY BOULNOIS seconded.

Mr. PEACH thought that the reserve fund was increased unnecessarily, and that the profits available for distribution among the shareholders were thus unduly curtailed. He moved an amendment, in effect, increasing the dividend payable on the Ordinary shares, remarking, however, that he brought the amendment forward more with a view of discussion on the subject than with any idea of getting it carried.

The CHAIRMAN said he could not put the amendment, because a larger dividend than that recommended by the Directors could not be paid.

Mr. PEACH (continuing) said that a reserve fund, as he understood it, had three uses—for equalising dividends, for providing against contingencies, and for providing capital for the purposes of the business at a time when it might not be possible to raise money on advantageous terms on the outside market. He thought the existing reserve fund was more than ample for the first two purposes, and that so long as any extension that was proposed was legitimate, there would be no difficulty in raising the capital that might be required.

A SHAREHOLDER pointed out that another use of the reserve fund, which Mr. Peach had overlooked, was to strengthen the financial position of the Company, and to enable the Directors better to meet competition.

Another SHAREHOLDER remarked that a very important point in connection with their having a good reserve fund was that it might enable them in a few years' time to pay off their debentures—a measure which would place the ordinary shareholders in a much stronger position.

The CHAIRMAN then put the motion, and declared it carried *nem con.* He afterwards proposed the declaration of dividends for the half-year ended December 31st last, at the rate of 6 per cent. per annum on the Preference shares, and at the rate of 10 per cent. per annum on the Ordinary shares. He remarked, with reference to the discussion which had just taken place, that some would always think that it was better to pay a larger dividend than to carry forward so much, while others would maintain, with equal force, that it was better to carry forward a larger amount instead of paying a higher dividend. Speaking as a Director, however, he might state that the possession of a good reserve fund greatly eased the responsibilities of Directors and facilitated their work if they had to go to their bankers.

Mr. R. S. ERSKINE seconded the motion, which was carried unanimously.

Sir Gilbert Augustus Clayton-East, Bart., and Mr. Thomas Orger Lazenby, J.P., were re-elected as Directors, and Messrs. Cooper Bros. were afterwards reappointed auditors.

The meeting then considered resolutions for increasing the capital.

The DEPUTY-CHAIRMAN (Sir Gilbert Clayton-East) said he had much pleasure in proposing the resolution increasing the capital of the Company. It was intended to extend the works at Rugby and to procure more and more powerful tools they proposed to use part of the new capital. Another portion of the capital they proposed to use in starting boiler works at Queensferry, on the Dee, near Chester. They had been slow about their boiler, but the time had not been lost or wasted, and had now arrived for them to commence its manufacture with confidence. He concluded by moving that the capital of the Company be increased to £500,000 by the creation of 40,000 additional shares of £5 each, half in Six Per Cent. Cumulative Preference and half as Ordinary shares, ranking for dividend *pari passu* with the existing Preference and Ordinary share capital.

Mr. A. R. HOLLAND seconded the motion.

Mr. PERCY HUNTER doubted the wisdom of imposing on the existing successful business additional capital in order to develop the boiler. He suggested that the boiler part of the business might be conducted by a separate company.

The CHAIRMAN said the work which had been done with the boiler hitherto had been experimental, but there was not the slightest notion of experimenting at the proposed new works. He believed the physiological moment for bringing out the boiler had arrived. He believed they had a most valuable property in their boiler, which would make profits quite out of proportion to the capital invested in it. The administrative expenses connected with the new enterprise would be small.

The resolution was carried *nem con.*

It was also resolved that the new shares should be issued at such times and at such premiums as the Directors should determine.

A meeting of the holders of the 30,000 Preference shares was held subsequently, at which it was resolved that the Company be empowered to create and issue the new Cumulative Preference shares ranking for dividend, and in all other respects, with the existing Preference shares in the Company.

A cordial vote of thanks to the Chairman and Directors brought the proceedings to a close.

National Electric Free Wiring Co. (Limited).

The first ordinary general meeting of this Company took place on Friday last, under the presidency of Mr. R. STEWART BAIN.

The SECRETARY (Mr. Percy B. Wilson) read the notice convening the meeting, and the report and accounts having been taken as read,

The CHAIRMAN said: Gentlemen, you will see from the report that the accounts are made up from the inception of the Company—that is to say, from the time of our taking over the business of the Electric Free Wiring Syndicate in July, 1897—to December 31, 1898, but as we did not start work until about the beginning of October, 1897, they really only cover a period of 15 working months. During that time we completed 976 installations, with an aggregate of 24,498 8 c.p. lamps. Of these 680 were free-wired installations and 296 were for ordinary contract work. The free-wired lamps numbered altogether 24,498, and the contract lamps numbered 9,623. We had in hand at the end of the year 423 orders, with the aggregate of 13,224 lamps, and since the books were closed we have received orders for 293 installations, with the aggregate of 5,563 lamps. Considering that the business is a new one, I think we have every reason to be satisfied with the progress it has made and the prospects it holds out for the future. In addition to the contracts we took over from the Syndicate, further free wiring contracts have been completed during the period under review with the Taunton, Canterbury and Lincoln Corporations and with the Blackheath and Greenwich, Fleetwood, and Prescot Electric Supply Companies, and since the end of the year we have completed contracts with the Corporations of Tunbridge Wells and Redditch and the Salisbury Electric Supply Co, and other contracts are in course of negotiation; in fact, we have heard this morning we have received another one. You will see from this that the business is increasing in a satisfactory manner. We have opened branch offices at Peckham, Shoreditch, Blackpool, Bradford, Canterbury, Lincoln, Prescot, Redditch, Taunton, Worcester, Tunbridge Wells and Salisbury. If you will turn to the accounts, you will see that during the period under review, our total revenue amounted to £3,244. 11s. 3d., and, of this amount, £735. 6s. 4d. represents the amount we received from revenue from the free wired installations. As we shall probably look to this item as our principal source of revenue in the future this amount does not, perhaps, look very large, but a more favourable aspect is put upon it when I tell you that out of 680 installations completed at the end of the year only 85 had been completed for a full year, and consequently had borne revenue for that period, the remainder having been completed during varying periods—a large proportion during the last quarter of the year—and that the revenue for the last quarter of the year amounted to nearly one-half of the total amount shown under this head. It will be apparent, therefore, that, having commenced the present year with 680 installations, all of which are revenue-bearing, our receipts from this source during the present year will show a considerable increase. Our profits from contracts and sales amount to £2,037. 4s. 4d. The Board consider this is satisfactory, considering that the business is a new one and that our men had to be trained to use the system of wiring. We have carried out some important contracts, as, for example, the wiring of the new General Post Office at Liverpool—the second largest in the kingdom—the West Ham Technical Institute (for the West Ham Corporation), the Derby Technical Institute (for the Derby Corporation), the Metropolitan Fire Brigade Headquarters (for the London County Council), and many others, and in almost every case our work has given complete satisfaction. We have had complaints—every new business must have complaints—and considering the difficulties we had to overcome in training our men to practically new system of

Digitized by Google

wiring and the difficulty we have had in obtaining suitable men, I think we have done exceedingly well to have had so few. These complaints have now almost entirely disappeared, and we have lately received some excellent testimonials as to the quality of our work. Our system meets all the requirements of the new wiring rules which have been formulated since the introduction of the high-voltage system by various lighting authorities, and it is equal, if not superior, to any system for efficiency and durability. The work has been carried out at less cost than the figures in the prospectus, although we have installed a larger proportion of 8 c.p. lamps than we anticipated. The cost of installing an 8 c.p. lamp is practically the same as installing a 16 c.p., although the revenue received from a 16 c.p. is nearly double. The amount received for interest and discount was £414. 18s. 1d., and the greater part of this item was the interest received on money we had on deposit. We have only called up 10s. per share, and of this we had at the end of the year £20,000 on deposit. Our balance would have been less than this if we had not received some large payments on account of contracts towards the close of the year; but we were fortunate in placing the money at very good rates of interest during the time that money was comparatively dear. I might mention here that we hope to have a new source of revenue to show in this account next year. We find a number of people object to free wiring, but cannot afford to pay for the wiring of their houses in one sum, and for this class of customers we have adopted what is commonly known as the hire-purchase system, by means of which customers may become the possessors of their installations on easy terms of payment extending over one, two, or three years. Of course, these payments are under proper guarantees, and we have already every reason to be satisfied with the success of this new system. If you will now look at the debit side of the account you will see that the management expenses were £1,330. 7s. 10d., after charging the proportion of the expenses to free wired installations in accordance with the conditions of the agreements we have with lighting authorities. This proportion was carefully ascertained, and, after being checked by our auditors, carried to the proper account. The next item is Directors' fees. The Directors are entitled to £1,750 for the period, but the Board are more concerned in the ultimate success of the Company than in drawing the full fees to which they are entitled. (Hear, hear.) We have agreed to relinquish £1,375—nearly four-fifths of the total—and the amount drawn about recoups us for the out-of-pocket expenses in attending to the business of the Company. We have considered it prudent to at once commence writing off amounts for depreciaton. The prospectus stated that before a dividend was paid a sufficient amount was to be set aside yearly to form a sinking fund. We have not waited until we paid a dividend before commencing to write off certain amounts for depreciation, &c., and in writing off this amount of £233. 11s. 8d., our auditors are of opinion that we have done all that we could be reasonably expected to do in the first year. The balance (£1,222. 8s. 3d.) is, perhaps, better than it looks at first sight. The total amount of capital we have received is £51,060, out of this we had to pay £11,149 in cash to the vendors, and as we had £21,838. 17s. 7d. in hand at the end of the year, this leaves a sum of about £18,000, which we have used as working capital. Of this £14,000 was in our possession, and used by us for 17 months and £4,000 for five months. This balance of £1,222 would, therefore, nearly represent 6 per cent. per annum on the total capital employed and rather more than 2½ per cent. per annum on the total capital called up, a result which I hope you will consider fairly satisfactory on the first year's working of an entirely new company, for which the business had to be made. The Board consider it would be prudent to carry this amount forward to the credit of the current year. I have already referred to the principal items in the balance-sheet. The items I have not referred to are Stock at head offices and branches (£3,521. 0s. 9d). This is the amount of Stock certified by our manager and district managers at the various branches. The item of £3,951 represents the amounts due from our customers up to the end of the year, and are all certified as being good. I now formally move "That the report and accounts be received and adopted."

Mr. J. W. SWAN seconded the motion.

A SHAREHOLDER asked what was the object of calling up the second 5s. per share if there was not to be any use made of the money.

Mr. A. E. FRANKLIN asked how it was the profits appeared so small on the contract business, that 296 installations only produced a revenue of £2,000, considering the very large installations that had been in existence, and said he thought it would interest the shareholders to know what percentage of profit was made on these contracts.

The CHAIRMAN replied that the balance of £21,838 would have been considerably less if the Company had not received towards the end of the year considerable sums on account of large contracts which had been completed. The Board did not consider it desirable to distinguish in the accounts between the profits from the sales and from the contract work, because they did not wish to give their trade rivals information as to the profits that had been made on the contracts. On some of the large contracts completed in the early stages of the Company's existence only small profits were made, but they did not look for large profits in the early stages of their undertaking. The Government was satisfied with what had been done at the Liverpool Post Office, and he hoped it would lead to their receiving other contracts.

The motion was then put and carried unanimously.

The retiring Directors (Mr. James T. Jervis and Mr. W. R. Davies) were re-elected, and the auditors (Messrs. Monkhouse, Stoneham and Co.) re-appointed.

The meeting then became extraordinary for the purpose of considering a resolution—"That the name of the Company be and it is hereby altered from the National Electric Free Wiring Co. (Limited), to the National Electric Wiring Co. (Limited)."

The resolution was carried unanimously and a vote of thanks to the Chairman terminated the proceedings.

County of London and Brush Provincial Electric Lighting Co. (Limited).

The fifth ordinary general meeting of this Company was held on Monday, under the presidency of the Right Hon. Lord RATHMORE.

The SECRETARY (Mr. H. B. Renwick) read the notice convening the meeting.

The CHAIRMAN said: The report and accounts having been taken as read, I now propose their adoption. In doing so I hope that you will all agree that the story we have there told you is, on the whole, very satisfactory and encouraging in the proof it gives of steady progress in the development of the business and of the policy of our Company, and encouraging in the hopes it holds out of substantial results in the near future and of the still greater successes which we believe will ultimately follow. Of course, as you all know, this Company is still passing through that transition stage through which all undertakings similar to ours have had or have to pass, and during that transition stage checks, delays and disappointments are more apparent, and are more severely felt, than when the undertaking attains maturity. As to the accounts, the capital expenditure on our London stations amounted during the year to £148,798; but of that sum £104,906 was on account of mains, transformers, motors, and meters, of which £45,322 was in respect of Camberwell, and £12,828 of Eastern Holborn, much of which expenditure is, for the moment, necessarily not productive. In the case of Camberwell it is unproductive to any extent at present, owing to the delays which we encountered in obtaining access to that district—delays over which we had no control—and in the case of Eastern Holborn, on account of the fact that the supply has only been available for so short a time. But I am glad to say that those obstacles have now been overcome in Camberwell, and both in that district and in Eastern Holborn we anticipate satisfactory returns. "Expenditure on buildings" (£13,479) was the greater part in respect of works which were really carried out in 1897. The item of £20,395, under "Sundry debtors," are debts principally for current supplied to consumers, and interest and dividends owing to us by our associated companies. They were all good debts, and since the end of the financial year have been almost all collected. On the other side, "Sundry creditors" and "Bills payable," £45,007 are in respect of cables, conduits, and various kinds of machinery, as well as of other small accounts incidental to the ordinary working of our business, and they have either been already paid off, or are very shortly to be. "Loans against security" amount to £101,000, and this represents temporary advances which we have had from our bankers. Owing to the favourable state of the money market, and also, to a great extent, to the wise and able advice of our Vice-Chairman, Mr. J. B. Braithwaite, jun., those advances were obtained at very favourable rates of interest, and they have now been considerably reduced. With regard to our London stations, I will ask you to bear in mind that a great deal of the expenditure has been up to the present necessarily unremunerative. As time goes on that expenditure becomes daily more reproductive. Nevertheless, you will see that a gross revenue of £22,261 has been contributed from our two London stations, and that is after allowing for the considerable rebates which we make to some of our customers. I think you will agree that this sum of £22,261 is almost as much as we could fairly have expected from these two stations, bearing in mind, of course, what is the real key to the situation—that last year, 1898, was really the first completed year of working in the case of both stations. Coming to the net revenue account, so far as the North London station is concerned, I must frankly say that the proportion of net revenue to gross earnings is not very satisfactory, but there were many causes which contributed to this untoward result. In the first place the fuel bill, for reasons upon which I need not dilate, was much larger. Then the station lighting is also rather larger than we like to see. That was caused by the necessity of carrying on construction works during the night. Repairs is a rather large item, but I believe these repairs were of rather an exceptional character. But putting all those—what I would call rather excessive and accidental expenses—together, a considerable sum is arrived at, which would no doubt have gone to swell the net revenue of the North London station. One unsatisfactory item, rates and taxes, comes to nearly £1,000, or 10 per cent. of the gross earnings. However, on the other hand, I am glad to say there has been a saving already this year in the fuel bill in the North London station of ¼d. per unit, and Mr. Lawson, our engineer and manager, hopes before the end of the year this saving may amount to ½d. Turning to Wandsworth station, we consider the result of the working there altogether satisfactory, because we find that out of a total of £11,042 received £4,958 was clear profit, and at this station, again, we hope that further economies may be effected. Testing the case by the amount of sales of current, our engineer and manager estimates the sales in both St. Luke's and Holborn for the present quarter (March) will be equal to those of December quarter, generally by far the best quarter of the year, and he also expects that a like rate of progress will be maintained to the end of the year. If that expectation is fulfilled, he further estimates that the result of the sales of current in Wandsworth during the present year will be double what they were in 1898, and that in St. Luke's they will be three-fourths more. If these estimates should be fulfilled the result will be that, on the working this year, there will be a very much larger proportion of net revenue to gross receipts, as compared with last year. I, therefore, think that, although it cannot, perhaps, be said that the result of the working for the past year of our two London stations appears very large in the accounts, still last year was really the first completed year of those stations. Our policy has been to build and equip these two powerful stations in the best way possible, and to supply current from the mains in every part of the district we have secured which seems likely to be productive. The principal mains have now been laid or are being laid throughout all our districts in north and south London, and therefore, in the future, as custom arises, it will only be necessary to go to the expense of a short amount of subsidiary mains to connect that demand

Digitized by Google

with the principal mains. I should like also to refer to the demand for and supply of current for power purposes; and here I may say that we have made rather a new departure. We have installed at our St. Luke's station, a plant to generate continuous current at sufficient pressure for distribution throughout the whole of our North London system, and in such a way that the cost of conductors afterwards will be but small. Already the results are, I think, satisfactory and encouraging, because we have had applications for motors amounting to the equivalent of about 300 H.P., and inquiries for several 100 H.P. additional; and negotiations for even larger supplies are under consideration. I need hardly point out what a great advantage such a source of custom will be in those stations where for lighting purposes the load in summer must necessarily be rather a light one. I must now refer to the Bill we have introduced into Parliament in connection with our London stations. That Bill will enable us to cope much better with the demand for current already developed, and which promises to become still greater in our existing districts, and also, of course, in any districts which we may hereafter acquire. It will also enable us to cross the intervening spaces which separate our central stations from our outlying districts. The Bill has passed its second reading in the House of Commons, and is now before a Committee, and I can say that we feel pretty confident the Bill will soon pass into law. Finally, with respect to our London station we hope when the next annual meeting comes round that all our mains will have been laid in the Camberwell, St. George the Martyr, and the St. Olave districts, and will have begun to bring in a substantial revenue to the Company. In the case of Camberwell there is a residential district which corresponds very nearly with the residential district of Wandsworth, of which we have had so good an experience, and in the northern part of the Camberwell district and in the districts of St. Olave and St. George the Martyr, we expect also rather a brisk demand for power. On the north side we expect also that the mains will by this time next year be laid through Western Holborn, and we hope to derive a substantial revenue from all these districts. Now, as to our provincial stations at Richmond, Dover, and Bournemouth. I always held that our investment at Richmond would turn out a good one, and that expectation has been most entirely fulfilled, for during the past year the Richmond Company, besides placing a considerable sum to depreciation account, and paying off a large part of the balance of losses on the working of the station before it came under our control, have been able to declare this year a dividend of 4 per cent., against 3 per cent. for last year. We have no doubt that the prospects of the Richmond station are excellent, and that our investment will considerably increase in value. As to Dover, the progress there has been very satisfactory. Here the gross revenue has increased by over £1,000. The remainder of the Ordinary shares, amounting to about £25,000, have been issued, part being allotted to this Company, and dealings in these shares have taken place at a premium of more than 20 per cent. Here, again, we feel confident that the value of our investment will considerably improve. As to Bournemouth, at the end of 1897 we transferred our shares in the old Bournemouth and District Company to the new Bournemouth and Poole Company, reserving for ourselves a considerable interest in the shares of the new Company. I am glad to tell you that there has been a rapid advance in the revenue of the Bournemouth and Poole Company, and they have been able to declare a dividend of 4 per cent. for the past year. There can be no doubt at all that, as time goes on—and especially in this current year—the value of that investment will also be considerably enhanced. It is evident that in these provincial stations we have very valuable assets; and several inquiries have been made to us already as to whether we would be disposed to part with our interests in those provincial companies. We have thought it better—and I hope you will agree with us—not to avail ourselves of these overtures, at any rate, for the present. I hope what I have said will have justified the view I took of the progress, the present position, and the prospects of our Company. A little while ago we applied for £200,000 in debentures at 4½ per cent., and offered £100 at £108. The issue was subscribed for nearly nine times over; the total amount offered to us for our £200,000 was £1,721,000. I think that that was very satisfactory. We were sorry it was not possible to give a larger proportion than we did to our own shareholders who applied. We must all regret that we have not been able to recommend a dividend for the past year, but that is an experience which has fallen to the lot of every company similiar to ours which has had anything at all of the same experience to go through. However, that period of preparation and probation for us is now almost ended, and we may look forward with confidence in the future to constant, steady and substantial success.

The DEPUTY-CHAIRMAN (Mr. J. B. Braithwaite, jun.) seconded the resolution, and said: You will all feel that the working of our London station is the key of our position. Our provincial investments have turned out extremely well, and no doubt we shall get substantial profits from them, but the future success of this Company must, after all, depend on the working of our London stations. If you compare what we earned at our London stations last year with what we earned this year, you will see that, broadly speaking, we have now doubled our net profit. Last year we earned £3,802. 14s. 10d., and this year £7,117. 12s. 1d. With respect to St. Luke's itself, we only commenced working at the beginning of October, 1897, and, therefore, that year's results only showed three months' working. For the previous nine months we obtained current from an adjoining company at wholesale prices and sold it at retail prices, naturally making a certain profit on it. This past year we have had to work the station for the twelve months, and the local authorities kindly put up our rates by about £1,000. The fact that we came out so nearly the same as we did last year, when we only bore the expenses of working the station for three months, is rather significant and decidedly encouraging.

Mr. HOLLAND said he had gathered from what had been said that the supply of power would play an important part in their Company, especially in St. Luke's and Clerkenwell. He understood that other companies were supplying electricity for power from their lighting plant and with the same mains, but that their Company had a special generating plant for electricity for power from special mains. Of course, this meant additional capital expenditure, and occupying of more room at the stations, which might ultimately be wanted for lighting purposes. He thought a little further information about it would be interesting. In the revenue account the item of gross profits stood at £3,996 and dividends receivable at £2,562. He took it these items represented the whole of the income derived from the associated companies, and the amount together was £6,558, against £7,767 in 1897. He noticed the investments in the associated companies had been increased by £34,178, and there were four associated companies.

Mr. LEIGHTON thought they would seriously feel the loss of revenue when the South London Company ceased to take current from them.

Mr. TUCKETT said the sum of £10,000 figured as calls in arrear, and he thought the people owing this money ought to pay interest on it. He had always had, and he still had, great confidence in the Company's future. Could the Directors see their way for carrying out installation on a system of deferred payments, as some of the other companies had done?

The CHAIRMAN, in reply, said the system of deferred payments had been considered by the Directors, and if it were desired by a considerable number of customers, they would favourably consider the application. The £10,000 was only due for calls in arrear on Dec. 31. Their Wandsworth station, when the South London Company ceased to take current, would suffer to that extent; but, on the other hand, he had the greatest confidence in the development of Wandsworth, where everything had turned out as favourably as they had anticipated, and where the demand was steadily increasing. When Wandsworth supplied Camberwell, St. Olave's and St. George the Martyr, the results would be still better. With reference to the new system of supply for power purposes, they had been obliged to adopt it under their Provisional Order for St. Luke's district; but, apart from that in anticipating the great demand that there would be for other than power purposes, they fully believed that this would prove a good investment as the demand for current grew. As to the gross revenue from the associated companies, the reduction would, he thought, be accounted for when they remembered that the Company had parted with a considerable portion of their interest in the Bournemouth Company, and that the profit made by them on that transaction in 1897 really added considerably to their revenue account for that year.

He then put the motion, and it was carried unanimously.

A resolution confirming the payment of the dividends was carried unanimously.

Lord Rathmore and Mr. F. W. Reynolds were reappointed Directors, and Mr. R. H. Marsh was reappointed auditor.

A vote of thanks to the Chairman terminated the proceedings.

EASTBOURNE ELECTRIC LIGHTING CO. (LIMITED).—The ordinary meeting of this company was held on Monday. In moving the adoption of the report, the Chairman (Mr. G. Boulton) referred to the satisfactory nature of the balance-sheet. They had always met under agreeable circumstances, which were even more agreeable on this occasion, when they met to offer the shareholders an increased dividend. The motion was adopted. A cordial vote of thanks was accorded the officials of the company, Mr. H. W. Wilkinson and Mr. H. Towner, for their past valuable services. Subsequently an extraordinary meeting was held to consider an amended offer of the Eastbourne Town Council for the purchase of the company's undertaking. The Corporation agreed to pay a sum equivalent to £2 for every £1 of capital subscribed and to pay a sum of £2,000 compensation to the officers of the company in the event of their services not being continued. The Corporation would also accept responsibility for the new machinery under order and not supplied. The total amount of the amended offer is about £83,000. The company would retain their reserve and depreciation funds, and would themselves discharge certain liabilities incurred on capital account; the date for the transfer to be Jan. 1, 1900, the company having all benefit of the present year's trading. This offer was eventually accepted.

GAS, WATER AND GENERAL INVESTMENT TRUST (LIMITED).—At the meeting of this company, the chairman (Mr. J. B. Braithwaite) announced that the Union Electric Light and Power Co. (an American venture in which this trust is interested) had perfected their electrical arrangements. They had an electric installation which does what he thought was not done in any other place in the world. They had the Pioneer Company's power, which they got from Ogden, 30 miles from Salt Lake City; they had the power which belonged to them previously in the big Cottonwood Cañon, which was some 20 miles away, and they had steam plant which belonged to them and the Citizens Co., with which they had previously amalgamated in Salt Lake City itself. Their electrical engineer (Mr. Hayward) had, during the year, managed to perfect the system in such a way that he had now in one small room, what he called the conning tower of a battleship, where, by moving a switch, he could get his power either from Ogden, the Cottonwood Cañon or the steam plant, thus giving great reliability in supply, and one of the results of that reliability had been that they had recently secured as customers one of the largest smelting works in that vicinity, which were taking 200 to 300 H.P. entirely on the ground of reliability of supply. For the twelve months ended Oct. 31 last, the gross earnings were £50,000, the expenses about £30,000, and the net profit about £20,000. In order to pay interest on the prior lien bonds £7,500 a year was required, so that the company was earning a very substantial surplus over the amount required to pay interest on these bonds. There was no doubt that they had got a fine property in Salt Lake City, and if it were not so far away, and they had not quite so large an investment in it, he thought they might possibly regard it as one of their best assets.

ISLE OF MAN TRAMWAYS AND ELECTRIC POWER CO. (LIMITED).—The annual meeting of this company was held at Douglas on Friday last. The Chairman (Mr. Alex. Bruce) commented on the increasing sources of

Digitized by Google

revenue from the extension of the line from Laxey to Ramsey, and to the saving in expenditure which is expected by utilising water power, whereby the systems will be worked for eight months in the year without steam power.

LIVERPOOL DISTRICT LIGHTING CO. (LIMITED).—The annual meeting of this company was held last week. The directors' report stated that the company was now in a profit-earning state. The plant at the Waterloo generating station had been working up to its full output, and it would be necessary to increase the capacity of the station before next winter. The number of lights supplied at the beginning of the year was about 450 ; at Dec. 31 the equivalent of 2,059 16 c.p. lamps were connected, and orders had been since received for over 600 further. Owing to various causes the permanent plant at the Gateacre station was not connected up till the beginning of 1899. The number of lights there at the beginning of the year was about 200, which was increased at Dec. 31 to about 1,050. In order to meet the necessary expenditure upon these additions, a further call of £1 per share had been necessary. During the year the company had carried out a fairly successful contracting business. In October last the price of current in Waterloo was reduced from 8d. to 6d. per unit, when a system of free wiring was introduced. Since that time the number of lights supplied or on order had been nearly doubled, and further orders were being continually received. The number of consumers had increased during the year from 15 to 59. As the company had only been working twelve months, and most of that time under very light load, no provision had been made in the accounts for depreciation. The profit and loss account showed that the manufacturing and contracting business made a profit of £131. 11s. 5d., and the supply of electricity a profit of £11. 4s. 5d. The latter account set down £564. 19s. 4d. as cost of generation, £195. 1s. 3d. cost of distribution, and £230. 18s. 8d. proportion of general and management expenses, while the sales of electricity and meter rents brought in £945. 10s. 7d , and rents of property and service lines £56. 13s. 1d. In moving the adoption of this report, the chairman (Mr. A. H. Holme) said that the profit was certainly not very large, but the business was increasing, while the expenses would probably become little or no higher. Electric supply companies, when they became profit-earning, were not subject to such vicissitudes as railway and other companies. There was really a loss on the supply of electricity for the earlier part of the year, and the profit of the last three months had to be reduced to wipe off that loss. The low price at Waterloo had very much increased the consumption. They proposed to follow the same course at Gateacre from July 1 next. Their free wiring system was also one of the causes of the increased demand at Waterloo. Two new engines of the best type had been ordered for Waterloo, and would be ready by July to increase the supply. As to future profits, he thought they ought to be in a position to make between £1,200 and £1,500 next year. They had plenty of money to finish the work in hand and the mains in contemplation, but the time was coming when they must consider the desirability of extending their operations. They might increase their capital or issue debentures, as it was evident it would pay them to increase their business. The report was adopted.

RICHMOND (SURREY) ELECTRIC LIGHT AND POWER CO. (LIMITED).—The fifth ordinary general meeting of this company was held on Thursday last week. Mr. F. W. Reynolds, J.P. (chairman), presided, and said the steady progress shown in the company's business during the past three years has been maintained during 1898. The gross receipts were £5,119, an increase of £650. The gross revenue showed a corresponding increase, the figures being £2,874 for 1898, against £2,234 for 1897. Increased sums had been written off depreciation and suspense accounts, which amounted to £800, against £550 for 1897. Out of the balance (£1,340) a dividend on the ordinary shares at the rate of 4 per cent. per annum was recommended, leaving £129 to be carried forward. £6,452 has been expended during the year on capital account, making £51,246. £3,548 of the year's expenditure was in respect of mains. The equivalent of 2,840 8 c.p. lamps had been added to the mains during the year, against 2,387 during the previous year, making the total at Dec. 31 12,352. In order to meet this growing demand for current, considerable additions to the plant had been made during the year, including new boilers, and additional generating plant was now being installed. The members of the staff had always taken a special interest in the success of the undertaking, and the energy and ability of their engineer and manager, Mr. A. J. Lawson, and their secretary, Mr. H. B. Renwick, have greatly aided the development of the business. Considerable responsibility had been thrown upon Mr. M. Flemying, their resident engineer, during the past year, in consequence of the additional works referred to, but he had again proved himself equal to the occasion. Their best thanks were due to these gentlemen. The report and accounts were approved, and a vote of thanks to the Chairman terminated the proceedings.

ROBEY AND CO. (LIMITED).—The ordinary general meeting was held at Lincoln on Tuesday, the chairman (Mr. F. Andrew) presiding. The report stated that the profits showed a satisfactory increase, the output having been considerably greater. The outlay on labour-saving tools had been further increased, while the buildings and plant had been efficiently maintained out of revenue. The works were still fully employed with profitable orders, and future prospects were most encouraging. The directors have decided to recommend that the whole of the second issue of debentures be paid off, and that the whole of the remaining unallotted capital (2,327 shares) be offered at par to the existing shareholders, £5 per share only to be called up for the present. After allowing for depreciation, debenture interest, &c., there remained a balance of £24,147 available for division, and the directors recommended the payment of a dividend of 10s. per share, free of tax, on both preference and ordinary shares (£13,795. 14s.), placing to reserve £10,000, and carrying forward £351. 6s. The report was adopted.

NEW COMPANIES, STATUTORY RETURNS, &c.

AMERICAN AUTOMOBILE AND MOTOR CO. (LIMITED).—This company was registered on Feb. 28, with a capital of £80,000, in £1 shares (of which 60,000 are Preference), to manufacture, sell, let on hire and deal in motors of every description. waggons, carriages, &c., and to carry on the business of electricians, mechanical engineers, founders, &c. The first Directors are :—F. L. Gardner (chairman), A. Geiger, S. Schlesinger, Rene de la Ville Le Roulx, Baron Paul de Vilaine and Pelayo Soberano.

ANGUS ELECTRIC LIGHT AND POWER CO. (LIMITED).—This company was registered in Edinburgh on March 24, with a capital of £25,000, in £5 shares, to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of electrical apparatus. The first subscribers are: G. Scott, J. Mitchell, V. Story, M.D., J. Valentine, J. Aird, A. Middleton and D. Campbell.

ARGENTINA ELECTRIC TRACTION CO. (LIMITED).—This company was registered on March 22, with a capital of £500,000, in £5 shares, to enter into an agreement with the Anglo-Argentine Tramways Co. (Limited) to construct, equip, maintain and work tramways under contract or as owners, and by electric or other methods of traction, and to carry on the business of electricians, electrical and mechanical engineers and contractors, suppliers of electricity, &c. The first subscribers are :—E. A. Lazarus, J. F. Nauheim, Albert R. Monks, A. Clements, H. F. Charles, J. T. H. Hudson, and H. A. Bumpus.

AUCKLAND ELECTRIC TRAMWAYS CO. (LIMITED).—This company was registered on March 22 with a capital of £150,000, in £10 shares (of which 7,500 are Preference), to construct, purchase, or otherwise acquire, equip, maintain and work (by electrical, mechanical or other power) any tramways or railways in Australasia, and to carry on the business of tramway and railway proprietors, carriers of passengers and goods, electrical engineers, contractors, electricians, suppliers of electricity, and manufacturers of electrical apparatus. The first subscribers are :—Sir C. Rivers Wilson, G.C.M.G., C.B., Sir C. W. Fremantle, K.C.B., Emile Garcke, John S. Raworth, Stephen Sellon, George Stevens, and C. S. Drummond.

AUTOMATIC MAGNETO-ELECTRO IGNITION CO. (FRANCE AND BELGIUM), (LIMITED).—This company was registered on March 3, with a capital of £15,000, in £1 shares, to enter into an agreement with Messrs. F. R. Simms and R. Bosch, and to carry on the business of proprietors and manufacturers of, and dealers in, motors, motor and other carriages, vans, waggons, &c , carriers of passengers and goods, electricians, electrical and mechanical engineers, machinists, &c. The first subscribers are: F. K. Cheese, J. W. Scott, A. E. Heming, H. M. Scott, B. C. Joy, A. B. Agacio, and E. E. Lefebure. The first Directors are: Frederick R. Simms (chairman), Robert Bosch and C. Harrington Moore.

JOHN JENKINS AND SONS (LIMITED).—This company was registered on March 16, with a capital of £70,000, in £1 shares, to acquire and take over the business of ironmongers, electrical and sanitary engineers, &c , now carried on under the style of John Jenkins and Sons. The first directors are :—John Jenkins, C. J. Clark, S. M. Waterfield and J. Jenkins, junr.

LUX SYNDICATE (LIMITED).—This company was registered on Feb. 28 with a capital of £2,030, in £1 shares (of which 30 are founders), to carry on the business of electricians, electrical, mechanical, metallurgical and chemical engineers, suppliers of electricity, manufacturers of lamps, globes, &c., metal founders, &c. The first subscribers are :—Mrs. C. Webb, R. Webb, S. H. Mills, C. M. Caplen, A. J. Hardy, T. W. Johnstone, and A. H. Atkins. Mr. Harry Godfrey is the first Director.

M'LAUGHLIN AND HARVEY (LIMITED).—This company was registered in Dublin on March 15th, with a capital of 50,000, in £10 shares (1,500 Preference), to carry on the business of electrical, hydraulic and sanitary engineers, &c. Mr. H. M'Laughlin is the first director.

TELEPHONE AND SWITCHBOARD SYNDICATE (LIMITED).—This company was registered on March 27, with a capital of £10,000, in £10 shares, to carry on the business of financiers, promoters of companies, contractors for public works, &c. The first subscribers are: W. H. Sinclair, A. E. Cowley, J. D. Haddock, E. Chevalier, W. Cawthorne, C. E. Craig and E. Griffiths.

YORKSHIRE DISTRICT LIGHT RAILWAY SYNDICATE (LIMITED).—This company was registered on March 9, with a capital of £50,000, in £1 shares, to promote, construct, purchase, or otherwise acquire any railways, tramways, or any works, rolling stock, or materials in connection therewith, to build and maintain electric and gas works, telegraph and telephone systems, &c. The first directors are :—J.W. H.White, S.W. Meyer, B. Day and E. Sisterson.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (since Feb. 2, 1899). Price of silver 27 7/8d. per oz. (March 29). Consols (2¾ per cent.) 110¾—110 7/8 for money, 110 13/16—110 15/16 for account ; 2½ per cent. 103½—103¾ (March 29), Stock Exchange Settling Days: Consols, April 6 ; Stocks and Shares Continuation Days, April 11 and 25 ; Ticket Days, April 12 and 26 ; Pay Days, April 13 and 27 ; Mining Share Carry over Days, April 10 and 24.

BABCOCK AND WILCOX (LIMITED).—The directors' report states that the profit for the past half-year (after deducting amount written off purchase of business account) amounts to £53,422, to which is added £5,912, brought forward, making £59,334. The following dividends are recommended :—Six per cent. on the Preference shares (less tax) and 20s. per Ordinary share (free of tax). After placing £2,500 to reserve, the balance (£9,334) is to be carried forward. A subsidiary company has been formed

Digitized by Google

in Germany, under the style of the Deutsche Babcock and Wilcox-Dampfkessel-Werke Actien-Gesellschaft, to which the business of the Company in the German Empire and its German patents had been transferred as from July 1, 1898. The parent company has guaranteed a minimum dividend of 6 per cent. on the shares of the German company for five years.

CANADIAN NIAGARA POWER CO.—The Toronto *Globe* states that owing to the apparent inability of this company to fulfil the terms of its contract, at an early date a resolution will be passed in the Legislature to the effect that if the terms of agreement have not been complied with by Nov. 1, 1899, the concession shall lapse.

COMMERCIAL CABLE CO.—The directors' report for the year 1898, presented at the annual meeting held on 6th inst., stated that the net traffic earnings from cables and land lines increased $107,410 over the previous year. Out of the balance to credit of revenue there had been set aside $350,000 as addition to reserve, and $100,000 to the fund for insurance of stations, apparatus and repair steamer. The reserve now amounted to $3,037,103, and the insurance fund to $200,000. During the year there had been issued $2,000,000 Four per Cent. First Mortgage bonds. The proceeds from this issue had been partly expended in acquiring the undertaking of the Pacific Postal Telegraph Cable Co. and further extensions of land lines, adding to the land line system 3,449 miles of poles, 12,841 miles of wire, and 468 offices. After providing for all operating expenses and reserves, the balance of net revenue, including amount from previous year, amounted to $1,908,759, out of which had been paid interest on bonds and Debenture stock ($704,296), and dividends and bonus on capital stock ($800,000), leaving $404,462 to be carried forward.

DIRECT UNITED STATES CABLE CO. (LIMITED).—An interim dividend has been declared of 3s. per share free of tax (being at the rate of 3 per cent. per annum) for the quarter ending March 31, payable April 26.

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO. (LIMITED).—Notice is given that on April 11 there will be drawn for payment 473 Five per Cent. Australian Government Subsidy debentures in this company.

WILLIAM JAMES GLOVER AND CO. (Established 1818), LIMITED.—The following notice, in connection with the recent issue of the prospectus of this company has been sent to us for publication:—

"William James Glover and Co. (Established 1818), Limited, Warrington and St. Helens.—*Notice.*—You have our authority to state that in consequence of the action taken against this Company by Messrs. W. T. Glover and Co. (Limited), of Salford, challenging the right of this Company to use the name 'Glover,' as applied to 'Electric' cable making, although the firm of Wm. Jas. Glover and Co. has been established for over 80 years, and long before Messrs. W. T. Glover and Co. came into existence, no allotment of shares will take place on the numerous applications sent in, and the money received on application will be returned forthwith.—Yours truly, WILLIAM JAMES GLOVER AND CO. (1818), Limited, F. G. FAIRHURST, secretary. By order of the Directors."

GREAT NORTHERN TELEGRAPH CO. (LIMITED).—The ordinary general meeting of this company will be held at Copenhagen on April 29.

NORTHERN COMMERCIAL TELEGRAPH CO.—A meeting of the provisional directors of this company will be held on April 11 at the offices of Mr. A. Fergusson, Q.C., Carlton Chambers, Ottawa, Canada.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed April 6 as a special settling day in 233,334 £1 fully-paid Five per Cent. Cumulative Preference shares (Nos. 526,667 to 750,000) of *Doulton and Co. (Limited)*; Wednesday, April 12, for 5,530 £5 fully-paid Vendors' Six per Cent. Cumulative Preference shares (Nos. 1 to 5,530) and the further issue of 7,500 £5 fully-paid Six per Cent. Cumulative Preference shares (Nos. 20,001 to 27,500) of the *British Insulated Wire Co. (Limited)*; and Thursday, April 13, for £167,900 Five per Cent. Debentures (Nos. 822 to 2,500) of the *Brisbane Tramways Co. (Limited)*. These debentures have also been ordered to be quoted in the Official List.

NOTES.

WE have received from Prof. J. A. FLEMING a copy of a wireless telegram sent to him by Signor MARCONI from Wimereux, near Boulogne. The message runs as follows:—"To Professor Fleming, University College, London. Glad to send you greetings conveyed by electric waves through the ether, from Boulogne to South Foreland, twenty-eight miles, and thence by postal telegraphs.—MARCONI." Since the receipt of this telegram Prof. FLEMING has been experimenting at the station at South Foreland lighthouse, and an account of his experience there, together with some pertinent observations on the subject generally, are embodied in a letter which we reprint from *The Times*. We heartily endorse the PROFESSOR'S view that the time has arrived for a little more generous appreciation of Signor MARCONI'S work by his scientific contemporaries.

WHEN it is remembered that MARCONI freely admits that his system of telegraphy is founded on a scientific basis which he did not discover, but did utilise and apply to practical purpose, the jealousy that has been scarcely concealed in certain scientific quarters is not to be condoned. Just as the work of OERSTED, FARADAY, DANIELL and other scientific workers detracted nothing from the merit of practical originality in the inventions of COOKE and WHEATSTONE, as telegraphists, of the early inventors of dynamo machinery—too numerous to enumerate—and of BELL and HUGHES, in the field of telephony; so the scientific labours of HERTZ and his successors leave an abundant meed of praise for the practical success attained by MARCONI in applying their discoveries to commercially useful purpose. Had MARCONI not justified himself as a "practician," he would thus far have established no claim to recognition. The success of his efforts not only differentiates him from his contemporaries, it also elevates him to the proud position of pioneer of the new telegraphy.

ALREADY, however, one of the practical limits to wireless telegraphy, as at present practised, is making itself manifest in the Marconi group of signal stations to the south-east of this island. "At present," writes Prof. FLEMING, "all signals sent from the South Foreland to France affect the receiver on board the Goodwin lightship." The PROFESSOR thinks that this "offers no difficulty," and he suggests a means for discriminating between the signals. There is a difficulty left untouched, however, in the impossibility of sending messages simultaneously and independently to or from the lightship and France. An uninterrupted stream of messages between the stations on opposite sides of the Channel would render completely useless the apparatus on the lightship, which would never be able to get a word in anyhow. Curiously enough, the first intimation at Wimereux that the apparatus erected there was in working order took the form of harmless eavesdropping, the messages between the two older stations being overheard; indeed, the Wimereux staff read off the message "We are going to speak to Boulogne at five o'clock"—this having been sent from the lighthouse to the lightship.

THIS result, of course, had been foreseen; but its actual occurrence emphasises the need for a means for confining a Marconi message strictly to its proper path. The sphere of influence of a wireless telegraph station has a fatal tendency to become too literally spherical. Messages scattered broadcast not only waste energy by travelling with futile persistence towards celestial space; they do positive mischief by interrupting the everyday business of irrelevant stations in the vicinity. If the Marconi waves would confine themselves strictly to business, the prospects of wireless telegraphy would be enormously brighter than they now are. We are not without hope that ere long a satisfactory method of thus restricting their activity will be discovered.

CURIOUSLY enough, the diffusion of ether waves which constitutes the defect just described is, in another application of wireless signalling, one of its most valuable features. We refer to danger signalling from lighthouses, &c. By a striking coincidence the commencement of cross-Channel wireless

Digitized by Google

telegraphy, and its successful performance even through many miles of sea fog, has taken place simultaneously with one of the most lamentable wrecks of recent years—the loss of the "Stella" on the Casquets. Were every island lighthouse surrounded by a halo of warning ether waves, and every sea-going vessel provided with a simple but efficient apparatus responding to the presence of such waves, disasters of this description would occur with much less frequency. Nor is this the only danger which could be eliminated, for, by providing every ship with a transmitter as well as a receiver, the risk of collision between two vessels would by a similar process be minimised. Difficulties of detail, doubtless, there are in regard to the carrying out of this scheme, but the broad principle is almost self-evident. What is now needed is an authoritative, and preferably international, committee of inquiry as to the most efficient means of warning vessels of invisible danger.

Capt. B. Baden-Powell relates an anecdote, in a letter to *The Times* of Wednesday last, which illustrates the unusual character of any defect or breakdown at a Marconi station. He was staying at the French station at Wimereux at the time of the occurrence:—

> Through Mr. Marconi's kind hospitality I have had the opportunity of watching message after message pass throughout the day, at all times and under all conditions, transmitted by different senders, even including myself. Scarcely a single letter has gone wrong, even though experiments were frequently tried to test new instruments or altered dispositions. A little anecdote of my experiences may not be out of place as instancing the rarity and strangeness of a breakdown. About ten o'clock one night, we at Boulogne attempted to ring up the South Foreland. There was no reply. Doubtless, we thought, the attendant had quitted his watch for a few minutes. After an interval we rang again, but answer came there none. Could the instrument be out of order? A careful examination was made, tests were applied, but no fault could be detected. Could anything be wrong at the other end? Again and again we rang up, but all to no good. A fresh receiving instrument was installed and all the wires carefully overhauled. We went out into the black darkness of the night and tested and pulled at the vertical wire suspended from the great mast outside to make sure that was intact. An hour or more passed, the greatest anxiety being displayed by the three officials. It had to be owned that the system had broken down! And there we sat in blank amazement, utterly at a loss to account for this apparent disaster to that great system in which we had all put such faith. Suddenly the bell rang! A short formal message followed, and then, in reply to our eager enquiries, came forth the prosaic message "Have been away to supper"! That is an incident that is not likely to occur again, for I expect that the epicurean telegraphist has since had almost as anxious a *quart d'heure* as did Mr. Marconi that night.

We have sometimes wondered what could be the *raison d'être* of the Wembley Tower; and the explanation that it is in imitation of the Eiffel Tower only shifted back the difficulty without solving it. Only as we go to press does a rumour reach us which throws a flood of light on the question, and turns our perplexity into admiration. These gigantic structures, reminiscent of Mr. Wells' uncouth Martians, were predestined by thoughtful fate to serve as masts for Marconi stations, to provide wireless communication between London and Paris. At any rate it is rumoured that the Eiffel Tower is about to be used for telegraphing in this way; and, doubtless, it was only the present incomplete state of the Wembley Tower that led to the South Foreland lighthouse being selected in preference to that hideous disfigurement of an otherwise picturesque landscape north-west of London. Building Eiffel towers for Marconi stations would be as extravagant a proceeding, however, as burning down the house to get roast pig. So when the 1,100ft. mast talked of for London to New York telegraphy comes to be actually erected it will doubtless prove to be a much less substantial affair. By-the-way, we hear rumours even of this feat being attempted in the quite near future. Much, however, must depend on the success met with in the experiment about to be undertaken with the Eiffel Tower.

Wireless telegraphy an accomplished fact, wireless telephony obviously suggests itself to those seeking fresh fields and pastures new. Where Hertzian waves are made the vehicle, and the coherer is the means of receiving the transmitted energy, the difficulties of telephony are immensely greater than those of telegraphy. The high frequency of sound waves makes it impossible for any known form of coherer to respond to ether waves correspondingly frequent; while their irregularity, when speech is the sound to be transmitted, would render syntony impossible, even were transmission an accomplished fact. Rumour reaches us of successful wireless telephony in Belgium; but, from intimate acquaintance with the difficulties of the problem, we judge that the method adopted, if this rumour be true, was not one involving the use of the coherer. By leakage, or by magnetic or electrostatic induction, telephony without connecting wires is, of course, possible and, within limits, commercially practicable. Its range of usefulness, however, is greatly restricted. Indeed, the immediate prospects of wireless telephony would appear to be decidedly inferior to those of the Marconi system of telegraphy.

It is once more our unpleasant duty to point out the deficiency and imperfection of the knowledge possessed by Mr. Provand and his American correspondent with regard to matters telephonic in the United States. The £16 tariff at Baltimore, referred to in his letter in another column as being lower than the charges for cities of a similar size in England, is *not* lower, and is, moreover, for a *single-wire* service; a metallic-circuit connection at Baltimore costs $125—say £25—per annum. Mr. Provand appears to be quite unaware that the charge for an underground metallic circuit connection in Liverpool, Manchester and other large towns in this country is £10 per annum for the first connection and £8. 10s. for additional connections; and, moreover, that the tariff in London on a five-year agreement is £17 per annum for one metallic circuit line, £12. 15s. for each additional line, and £10 for private houses. The extremely low charges quoted by Mr. Provand are admittedly those charged by the "independent" companies in the United States, for connection to small exchanges which serve limited areas and have practically no facilities for interurban communication. Only a small proportion of the telephonic business is in the hands of these companies; by far the majority is controlled by the American Bell Company, whose charges Mr. Provand admits to be higher than those obtaining in Great Britain and Ireland. The tariff at Baltimore appears also to be the lowest charge for a large city that Mr. Provand's correspondent has informed

Digitized by Google

him of. As to the question of municipal corruption, Mr. PROVAND puts himself to some pains to convince us that the municipal authorities in New York are corrupt in their dealings with the telephone company. Surely to place the local control of the telephone into the hands of the municipalities themselves will not lessen the danger of corruption. Further consideration of such matters as these is, however, outside the province of a technical journal.

THE first and all too brief public appearance of the Nernst lamp last February has given rise to expressions of opinion on all sides, both favourable and unfavourable, as to the possibilities of the promised rival to the carbon filament, arc and Welsbach lamps. Mr. T. J. JOHNSTON, a letter from whom will be found in another column, criticises the lamp with considerable harshness, and, we may even say, with some injustice. Although Mr. JOHNSTON attempts to show that the Nernst lamp has a past, we believe that this type of lamp has also a future, but it is not our intention at the present stage in the development of the lamp to consider such criticisms in detail—this task may be left to its introducers. We feel bound, however, to point out some inaccurate statements in Mr. JOHNSTON's letter. In the first place, he quotes us wrongly. We did not say that "Mr. SWINBURNE's neglect of the continuous current side" was "significant," but merely that he was reticent as to the relative merits of the lamp on continuous and alternate circuits. Then, of course, we cannot concur as to the prospect of an "apparent obsolescence of continuous current" in the near future. And lastly, Mr. SWINBURNE both exhibited and described "something better than spirit lamps and matches as igniters," and Nernst lamps were on view working at 100 volts and not 500 volts pressure. Such inaccurate statements as these certainly tend to lessen the force of Mr. JOHNSTON's criticisms.

Cable Interruptions.	Date of Interruption.
Paramaribo—Cayenne	Feb. 10, 1899
Cayenne—Pinheiro	Mar. 10, 1899

Electric Cabs in Paris.—Some 70 new electric cabs of the landau type were put on the Paris streets on Sunday, and were well patronised by the public.

The Proposed Memorial to Gaulard.—M. Sartiaux, president of the committee which has been collecting subscriptions towards raising a memorial to Lucien Gaulard, the transformer pioneer, announces that a sum of 2,560f. has been received.

The Nernst Lamp in Germany.—The *Elektrotechnische Rundschau* states that negotiations are in progress between the Allgemeine Elektricitäts Gesellschaft and the municipal authorities in Berlin, for a trial of the Nernst lamp for street lighting. It is proposed to light some avenues in the Thiergarten district by this means.

Electrical Patent Litigation in Italy.—La Compagnie Thomson-Houston de la Mediterranée has brought an action against the Leghorn Electrical Tramways Co. for infringement of its patents. The Leghorn plant was supplied by Messrs. Schuckert and Co., of Nuremburg, and the case has been adjourned for the latter to reply to the charges.

Paris-Berlin Telephone.—The negotiations for the establishment of direct telephone communication between France and Germany have resulted in an agreement on the main points. It is proposed to lay a line between Paris and Berlin, and another between Paris and Frankfort, and as the latter city is already in communication with Berlin, there will be two separate lines between the two capitals.

The American Government and Wireless Telegraphy.—It is reported that the American War Department is arranging to make tests with the Marconi system of wireless telegraphy. Two experimental stations have been selected, one on either side of the river Potomac, six miles apart, and the necessary instruments have been purchased. The experiments will be conducted by Col. James Allen and Lieut. George O. Squire.

Imponderable Jokes.—Writing to *The Times* of Easter Monday, Prof. J. A. Fleming, in an interesting letter on "Wireless Telegraphy," states that "messages, signals, congratulations and jokes were freely exchanged between the operators sitting on either side of the Channel." The imponderable ether would surely refuse to transmit any other than light and airy humour. Jokes sent between Marconi poles should not lack *point*.

Trinity House and Wireless Telegraphy.—The Deputy-Master of Trinity House, with a committee of Elder Brethren, accompanied by Lord Rayleigh, the scientific adviser, and Captain the Hon. F. C. P. Vereker, of the Board of Trade, visited Dover during the past week, with the object of making an official inspection of the wireless telegraph system as experimentally in operation between the South Foreland lighthouse and the East Goodwin lightship.

Modifications of the Nernst Lamp.—A patent has been field in the United States by Mr. W. S. Hadaway, Jun., for an *arc* lamp, the arc of which is closely surrounded by a sleeve of magnesia. The light of the arc is said to be augmented by the incandescence of the magnesia sleeve. The sleeve is constructed by fusing magnesia in the electric furnace, the resulting crystals being then ground to powder and mixed in a plastic mass with magnesium chloride. This mixture is then moulded under heavy pressure into the required shape, giving a structure of sufficient strength and durability to be supported wholly by the carbons, without any enclosing casing. Photometric tests of this lamp, with and without the magnesia sleeve, might assist in solving the problem whether the light emitted by incandescent lime, magnesia, Welsbach mantles, Nernst "filaments," &c., is merely that corresponding to the high temperature of the material as Mr. Swinburne holds, or is due to a property of the material itself, as most of the leading physicists agree. The same issue of the *Electrical World*, in which the above patent is alluded to, contains a letter, signed Theo. Reyman, describing a method he has devised for lighting the Nernst lamp. This involves a very similar application of the arc lamp to that just described. The apparatus is a series coil arc lamp, the upper carbon of which is raised by the magnet to strike the arc. Around the arc is placed a hollow cylinder of refractive oxide connected in shunt to the arc itself. This cylinder, when heated by the arc, is raised to incandescence and, becoming a conductor, increases the current through the series magnet, but diminishes that flowing through the arc. The increased current lengthens the arc and, owing to the smaller current through the latter, breaks it, and the light is then supplied by the incandescent oxide in the usual way. As the upper carbon is fed by gravity, it descends again into position for lighting as soon as the current is switched off from the lamp. No mention is made of the amount of power consumed in the series coil, which appears always to be in circuit.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

WEDNESDAY, April 12th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Telephones," by John Gavey.

THURSDAY, April 13th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Continuation of discussion on Mrs. Ayrton's Paper, "The Hissing of the Electric Arc." A Paper on "Experiments on Alternate Current Arcs by Aid of Oscillographs," by W. Duddell and E. W. Marchant, which has already appeared in the *Journal* will also be discussed.

FRIDAY, April 14th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Earth Currents and Electric Traction," by Prof. A. W. Rücker.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Wehnelt's Electrolytic Interrupter.—D'Arsonval communicates some new observations concerning the mode of action of Wehnelt's interrupter. He used a platinum wire 0·7mm. thick, projecting about 2cm. from the glass tube filled with mercury. He obtained Röntgen rays of a steadiness and penetrating power hitherto unknown, enabling him to obtain instantaneous radiographs of the hand. In conjunction with a Berthelot "effluviator," the coil worked by the new interrupter gave very large quantities of ozone. Determined by a revolving mirror, the frequency of the interruptions was found to be 1,700 per second. The best form of interrupter consists of a test tube with a platinum wire introduced through the bottom. Potash may be substituted for the diluted acid, and iron for the lead. The following is the author's theory of what takes place. By the passage of the current the platinum point is brought to a white heat. The heating of the surrounding liquid leads to the formation of a layer of non-conducting vapour round the platinum, which interrupts the current. Then the vapour condenses, the current is re-established, and the process repeats itself. This explanation, which makes the phenomenon analogous to the Trevelyan rocker, also explains why the interruption takes place in one direction only. For when the platinum point is positive it heats up quicker than when it is negative.

[D'Arsonval, *Comptes Rendus*, Feb. 27, 1899.]

Sensitiveness of Galvanometers.—Having had to measure very small currents by means of a Deprez-D'Arsonval galvanometer, C. Féry determined the ratio $r' : r$ of the resistances to be given to the torsion wire and the movable coil to ensure the greatest possible sensitiveness. The result differs according to the requirements of the operater. If the resistance r' of the torsion wire is given, then a maximum sensitiveness is obtained by making $r = r' + \rho$, where ρ is the internal resistance of the battery or other source of E.M.F. If the resistance r of the movable coil is fixed, a maximum deflection is only obtained when $r' = \infty$, so that this case is of no practical interest. Lastly, when the sum r and r' is supposed to be constant, so that the internal resistance of the galvanometer is given, a maximum sensitiveness is obtained by making $r' = 2r$. Now in the Deprez-D'Arsonval galvanometer r' is usually 0·5 ohms and $r = 200$ ohms. On making r' 132 ohms and r 66 ohms, the sensitiveness is increased no less than 153 times. This increase is, however, subject to a disturbance due to the magnetism of the copper of the moving coil. This source of loss may be eliminated either by employing a perfectly uniform magnetic field, or, as pointed out by Lippmann, by adding diamagnetic bodies to the movable coil sufficient to reduce its permeability to zero.

[Féry, *Comptes Rendus*, March 13, 1899.]

Carbon Coherers.—When brass filings are suspended in distilled water and a feeble current is sent through, with about 10 volts, the metallic particles form chains, which break up into rods on stopping the current. If they could be made to break up into individual particles, a result would be achieved analogous to what has often been attempted in the case of coherers. Noticing that the cohering particles showed signs of fusion, T. Tommasina experimented with an infusible body in the shape of carbon. He employed medium-sized grains of sifted arc carbon, and succeeded in preparing coherers of a sensitiveness quite equal to that of the best metallic coherers. Besides, these coherers lose their conductivity with the slightest shock, or even by the mere interruption of the current traversing them, though they do not appear to have the inestimable property of righting themselves when the electromagnetic waves cease. In that respect more may be hoped for from another type of carbon coherer also devised by the author. It consists of two round arc carbons mounted in a glass tube, and held in position by rubber stoppers. The rounded ends are lightly in contact. This coherer requires some "seasoning" before it works perfectly, but then it becomes exceedingly sensitive.

[Tommasina, *Comptes Rendus*, March 13, 1899.]

Current Intensity with Wehnelt's Interrupter.—H. Pellat has made the curious observation that when a Wehnelt interrupter is placed, first in an ordinary circuit, and then in a circuit containing an induction coil, the mean current intensity is increased, sometimes very considerably so. In one such case the E.M.F. was furnished by a battery of accumulators giving some 70 volts. On inserting the coil in the circuit an ammeter indicated 20 amperes. On short-circuiting the primary by a thick wire, the current fell to 15 amperes, to rise again on establishing the circuit as before. In another case, when some 110 volts were used, the current rose from 5 to 25 amperes, and a veritable flame passed between the two secondary terminals. Thus, the mean intensity of the current was raised by introducing an impedance. This fact, paradoxical as it may appear, is yet in accord with the known laws of induction. The author shows from the known formulæ that there are at least two possible ways of accounting for the phenomenon. Either the quantity $\frac{di}{R\,dR}$ is greater at opening than at closing, or the introduction of an impedance modifies the ratio of the open to the closed time.

[Pellat, *Comptes Rendus*, March 20, 1899.

Physiological Effects of Currents.—The study of the effect of currents upon the human economy is connected with one of the least cheerful applications of electrical science. But apart from their therapeutic value, their precise action in the case of accidents should be known, so as to facilitate restorative measures. As the result of some 170 experiments upon various animals, J. L. Prevost and F. Battelli conclude that high tension alternate currents applied to the head chiefly affect the respiration, and that the most valuable restorative lies in artificial respiration. In the case of low-tension currents, the ventricles of the heart are stopped, or are put into fibrillary tremulation, while the auricles continue to work. The remedy lies, curiously enough, in a short application of a high-tension current and in artificial respiration. That the high-tension current is a somewhat heroic remedy is shown by the fact that it stops the auricles while it allows the ventricles to continue beating. It must be applied, moreover, within 15 seconds (in cats and guinea-pigs, at least) after the low-tension shock, and that is not practicable, as a rule. Artificial respiration should always be tried in case of accidents. The authors could not establish any definite *post-mortem* characteristics of death by electricity, except intra-cerebral hemorrhage in case of prolonged applications.

[Prevost and Battelli, *Comptes Rendus*, March 13, 1899.]

Photo-Electricity.—In experiments undertaken for the purpose of investigating the nature of photo-electric currents, the highly sensitive silver halogens are usually employed. They have, however, the disadvantage of being converted into very unstable salts which cannot be satisfactorily isolated. G. C. Schmidt therefore employs the well-known oxide of copper, CuO, which, if it is modified at all, is converted into the lower salt Cu_2O, cuprous oxide. He deposits these salts on platinum foil, and immerses two such plates as electrodes in a solution of caustic soda. One of the electrodes is then illuminated with light of a definite colour, and the effect is studied by means of a galvanometer. Thus the experiment becomes readily accessible to Nernst's theory, which determines the E.M.F. from the solution pressure of the salt and the charge of the ion. But an important source of uncertainty is introduced by the fact that the potential of freshly-prepared layers of CuO rapidly decreases, going down to about half its initial value in 12 hours. When fresh CuO is exposed to red light it becomes positive, whereas it becomes negative under violet light. Hence red light increases the solution pressure of the oxygen. When pure metals are used in solutions of their own salts, under circumstances which exclude secondary effects, no effect is produced upon them by light.

MAGNETIC LEAKAGE IN THE ALTERNATING CURRENT TRANSFORMER.

BY ALEXANDER RUSSELL, M.A.

(Concluded from page 789.)

Calculation of the Magnetic Leakage.—From the results of experiment 16 in the preceding table we get α equal to 9·3deg. by (5), 10·9deg. by (6), 9·4deg. by (7) and 7·3deg. by (11). The first three of these results agree well with one another, but the last seems to show that the observed voltmeter reading on the secondary was too high. We shall take 9·3 as the leakage lag when the secondary current is 51·38 amperes.

Comparison of Observed and Calculated Leakage.

No. of experiment.	3	7	9	12	14	16
Calculated α	1·0	3·25	3·9	5·8	7·6	9·3
Probable α.....	0·5	2·9	4·3	6·2	7·9	9·3

The above values of α were calculated by the sine formula (5).

Calculation of Primary Angle of Lag for given Secondary Currents.

No. of experiment.	3	7	9	12	14	16
ϕ_1 observed	80·8	58·6	49·4	42·0	37·2	34·9
ϕ_1 calcu lated (no leakage) ...	80·8	58·1	47·8	37·3	31·8	27·9
ϕ_1 calculated	80·8	58·7	49·5	42·0	37·2	35·0

The second row has been calculated from the formula given in *The Electrician*, Vol. XXXVIII., p. 725; the third row from the formulæ given above.

Calculation of A_1 when A_2 is given.

No. of experiment.	3	7	9	12	14	16
A_1 observed	1·214	1·442	1·661	2·030	2·392	2·692
A_1 calculated (no leakage) ...	1·207	1·404	1·609	1·967	2·262	2·548
A_1 calculated.....	1·209	1·440	1·678	2·036	2·434	2·747

Comparison of Observed and Calculated Secondary Volts.

No. of experiment.	3	7	9	12	14	16
V_2 observed	102·0	101·7	101·4	100·8	100·1	99·7
V_2 calculated (no leakage) ...	101·9	101·6	101·3	101·0	100·7	100·5
V_2 calculated.....	101·9	101·4	101·0	100·4	99·8	99·2

Comparison of Observed and Calculated Primary Watts.

No. of experiment.	3	7	9	12	14	16
W_1 observed	469	1,804	2,583	3,632	4,571	5,297
W_1 calculated.....	464	1,796	2,615	3,632	4,652	5,401

W_1 has been calculated from $V_1 A_1 \cos \phi_1$, taking the values of A_1 and ϕ_1 calculated above.

Comparison of Observed and Calculated Efficiencies.

No. of experiment.	3	7	9	12	14	16
η observed.....	0·665	0·903	0·937	0·954	0·960	0·969
η_1 calculated (no leakage) ...	0·674	0·911	0·935	0·951	0·955	0·957
η calculated	0·674	0·911	0·935	0·951	0·955	0·957

η_1 has been calculated by the formula

$$\left(1 - \frac{151}{W_1}\right)\left(1 - \frac{16{\cdot}3W_1}{2{,}400^2}\right).$$

This is equivalent to the graphical construction for the efficiency. The last row η has been calculated from the more elaborate formula (12), which takes leakage into account, and we see that, as far as the third figure at least is concerned, up to five-sixths of full load it agrees with the graphical construction.

Calculation of the Efficiencies from the Observations on the Low Tension Side.

No. of experiment.	3	7	9	12	14	16
η observed.....	0·665	0·903	0·937	0·954	0·960	0·969
η_1 calculated (no leakage).....	0·674	0·912	0·936	0·946	0·948	0·951
η calculated	0·674	0·913	0·939	0·952	0·957	0·964

The second row has been calculated by formula (15), the third row taking leakage into account by formula (16).

Graphical Construction for the Primary Watts, &c., for a given Secondary Current.—(1) No magnetic leakage.

We suppose that V_1, W_0, A_0, and n are given. Draw two lines FB and FC at right angles to one another (Fig. 2). Measure off FD equal to $\frac{W_0}{V_1}$, and with centre D and radius equal to A_0 describe a circle cutting FB in B.

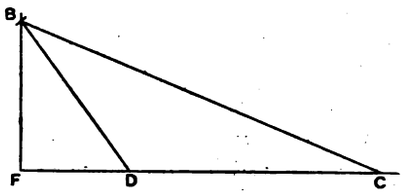

FIG. 2.

Then the angle BDF will equal the primary angle of lag on open circuit. To find A_1, ϕ_1 and W_1 for a given A_2, measure off DC equal to nA_2 where n is the ratio of the secondary to the primary turns and join BC. Then W_1 will equal V_1. FC, BC will equal A_1 and the angle BCF will be ϕ_1. Many interesting trigonometrical relations between the various quantities follow from this simple diagram (Fig. 3), but these may be left as an exercise to the student.

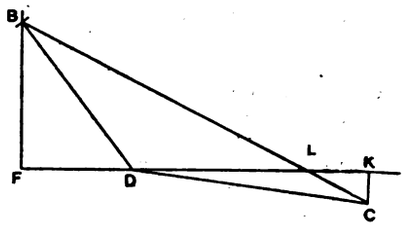

FIG. 3.

2. *Magnetic Leakage Considered.*—Suppose that α_1 is the leakage lag produced by the unit secondary current. The triangle BFD being constructed, as in the preceding case, make the angle KDC equal to $A_2 \alpha_1$ (α suppose) and measure off DC equal to nA_2 where n is the ratio of the effective secondary turns to the primary turns, found experimentally from formula (2). Draw CK perpendicular to FK then,

$$\begin{aligned} FK &= FD + DK, \\ &= A_0 \cos \phi_0 + nA_2 \cos \alpha, \\ &= \frac{W_1}{V_1} \text{ by formula (6).} \end{aligned}$$

Hence $W_1 = FK \,.\, V_1$.

Again $BC \cos BLD = FK,$
$= A_1 \cos \phi_1,$

and $BC \sin BLD = BF + KC,$
$= A_0 \sin \phi_0 + nA_2 \sin \alpha,$
$= A_1 \sin \phi_1$ by (5).

Hence $BC = A_1,$

and $BLF = \phi_1.$

For a given secondary current ϕ_1 is, therefore, greater when there is magnetic leakage. The locus of the point C for different values of W_1 is easily seen to be very nearly a parabola, touching FK at D, and hence the tangent to this locus at C will bisect DK nearly. In drawing the complete diagram this is a useful rule to remember.

Similar simple constructions can be given for the secondary voltage and also for the efficiency. These geometrical theorems are most useful, as by studying them various relations come out which are concealed by the often complicated algebraical expressions. They also suggest various laboratory methods of measuring the losses in the iron core of certain electrical apparatus.

The above method can be very simply applied to studying the air core transformer. The best way to write the differen-

Digitized by Google

tial equations in this case is as follows (adopting the usual notation):—

$$e_1 = Ri_1 + L\frac{d}{dt}\left(i_1 + \frac{M}{L}i_2\right).$$

$$-M\frac{d}{dt}\left(i_1 + \frac{M}{L}i_2\right) = Si_2 + \left(N - \frac{M^2}{L}\right)\frac{di_2}{dt}.$$

Written in this way they suggest the diagram shown in Fig. (1). In this case

$$\frac{BC}{BD} = \frac{L}{M}, \quad OC = V_1 \text{ and } OB = RA_1.$$

Numerous relations between the various quantities involved can be got which are independent of the shape of the wave of E.M.F. The tangent of the angle of lag in the secondary circuit always contains $N - \frac{M^2}{L}$ as a factor and hence vanishes when M^2 equals LN. Very simple geometrical constructions can also be given for the air core transformer whether at constant current or at constant voltage.

The constructions given in *The Electrician*, Vol. XXXVIII., p. 725, for "boosters," "pressure reducers," and "compensators" can easily be expanded in the same way so as to take leakage into account.

THE INDUCTION MOTOR.*

BY ERNEST WILSON.

(Continued from page 802).

Deal now with the armature of this motor. The armature being brought to the same position in each experiment by aid of the pulley-block, and the pull in pounds observed on the spring balance, observations were made for different positions of the phase of the primary potential differences E_1 E_2 and currents x_1 x_2; the potential differences between the ends of each of the armature circuits C, D, E (see Fig. 6), and the currents y_1, y_2, y_3, in each armature circuit. The electromotive force of each armature circuit, e_1 e_2 e_3, is given by correcting its potential difference for current into resistance of the armature coil. In this investigation, r_1 r_2 r_3 are respectively the resistances of the armature coils, and are each equal to 0·025 ohm; ρ_1 ρ_2 ρ_3 are the external resistances, in the armature circuits r_1 r_2 r_3, and constitute the independent variable. In any one experiment $\rho_1 = \rho_2 = \rho_3$. By correction for R_1 R_2 (the resistance of the primary circuit) into the instantaneous value of the current, the reactions $m_1 dI_1/dt$ $m_2 dI_2/dt$ have been found, and therefrom dI_1/dt dI_2/dt. An integration of the E.M.F. curves dI_1/dt dI_2/dt e_1/n_1 e_2/n_2 e_3/n_3 gives the average total induction in the coils where $n_1 = n_2 = n_3 = 24$. A small correction must also be applied in the case of the armature coils, since there are three groups of 24 each per half-period. If the distribution per half-period of $(\theta/2)$ along the surface circumferentially were a sine curve, the average total induction per coil would equal 0·93 of the maximum. In our case this coefficient is 0·93 nearly. The integrals of e_1/n_1 e_2/n_2 e_3/n_3 have been increased respectively by multiplying by 1/0·93 in order to deduce the maximum average induction experienced by each coil. Four distinct cases have been dealt with at about the same frequency of 52 periods per second, and with $\sqrt{\text{mean}^2}$ E_1 and E_2 equal to 60 volts. These correspond to values of $\rho_1 = \rho_2 = \rho_3$ equal to ∞ 1·03, 0·133 and 0·012 ohms. The results are given respectively in Tables V., VI., VII. and VIII. Table IX. gives the collected results.

Table V.

Angle in 60ths of a period.	A Circuit. $m_1 dI_1/dt$ Volts.	A Circuit. x_1 Amps.	B Circuit. $m_2 dI_2/dt$ Volts.	B Circuit. x_2 Amps.	$m_1 dI_1/dt x_1 + m_2 dI_2/dt x_2$ Watts.	e_1 Volts.	e_2 Volts.	e_3 Volts.

Frequency = 95·5. $\rho_1 = \rho_2 = \rho_3 = \infty$. $E_1\sqrt{\text{mean}^2} = 80$; $E_2\sqrt{\text{mean}^2} = 80$ volts.

Dealing with Table V. first, in which the armature is on open circuit, the relation between the curves dI_1/dt dI_2/dt and the E.M.F. curves e_1 e_2 e_3 may be found. Each of the $m_1\int\frac{dI_1}{dt}dt$ and $m_2\int\frac{dI_2}{dt}dt$ curves shows a maximum of $27·2\times10^6$ C.G.S. units; the coils on the armature experience each a total change of $7·2\times10^6$ C.G.S. units. We have, therefore, 27·2/75 as the total average maximum per turn due to primary and 7·2/24 as the total average maximum experienced per turn by secondary. Multiplying the former by 1/0·83 and the latter by 1/0·93, we have 0·437 and 0·322. The difference gives 0·115, which is 26·3 per cent. of 0·437. These results are given in Table IX., and also the corresponding ones for the other experiments, in which $\rho_1 = \rho_2 = \rho_3 = 1·03$, 0·15 and 0·012 ohms.

Torque.

Let f = frequency of supply; N = number of poles per revolution of stationary portion; there are two poles per circuit A and B to the period θ; r = radius of armature in cms. Then $2\pi r/N$ = length of circumference per half period in cms.; and $4\pi rf/N$ = velocity of field in cms. per second. Let l = length of armature core in cms. Let e_1, e_2, e_3 = the electromotive forces in volts of each circuit on the armature, and n_1, n_2, n_3 = the turns per circuit. Then $e_1/n_1 l$ = average volts per cm. length of conductor. Let y_1, y_2, y_3 = the current in amperes in the armature circuits. Without analysing the variation of B, the induction per square cm. at the conductor, we may say that during time $N/4\pi rf$ the average $e_1/n_1 l$ = av. $B\times 4\pi rf10^{-8}/N$. The force on the armature at radius r due to current y_1 in the conductor is $By_1/10$ dynes, if y_1 be in amperes; so that the

whole force on the armature at this radius due to one circuit $=Bn_1ly_1/10$, and taking B to be the average given by $e_1/n_1l\times N4\pi rf10^{-8}$ we get the whole force $=e_1y_1N/4\pi rf10^{-7}$. At the same epoch the forces due to the other circuits will be $e_2y_2N/4\pi rf10^{-7}$ and $e_3y_3N/4\pi rf10^{-7}$ in this three-phase armature. The average of the total force

$$\frac{N\times10^7}{4\pi rf}\{e_1y_1+e_2y_2+e_3y_3\}$$

over a half period, will be the average force acting at radius r upon the armature. In the ideal motor this force would have no variation. We must divide by 981×454 to reduce to pounds.

It will be well to see if this verifies by actual experiment. The torque has been measured for three values of $\rho_1=\rho_2=\rho_3$, the external resistance in the armature of this motor, namely, 1·03, 0·15, and 0·012 ohm, and found to be about 2, 7, and 21b. respectively at a radius of 3·5ft. Tables VI., VII. and VIII. give the results of the experiments in each case, and Table IX. shows the collected results, from which we see that the calculated values are 1·5, 6 72, and 2 21b. at a radius of 3·5ft. The agreement is as good as one could expect from the rough way in which the torque was measured, owing to the friction of brushes and bearings rendering an exact measurement difficult.

It is interesting to examine the effect of leakage field upon the distribution of power in this motor over a half period in time. The sum of $m_1\int x_1\frac{dI_1}{dt}dt$ and $m_2\int x_2\frac{dI_2}{dt}dt$ over half a period divided by $2f$ is the energy delivered to the motor by the primary circuit irrespective of $x_1^2R_1$ and $x_2^2R_2$ losses, since the potential differences E_1, E_2 have been corrected for x_1R_1 and x_2R_2. Similarly $\int e_1y_1\,dt+\int e_2y_2dt+\int e_3y_3\,dt$ divided by $2f$ is the energy received by the secondary or armature circuits. The difference gives the dissipation of energy due to magnetic hysteresis and induced currents in the iron (and copper if there be any) and that due to stray field. When the machine has open-circuited armature, the average rate of dissipation of energy in watts is 176 (*see* Table V.). Take Table VI., in which the external resistances $\rho_1=\rho_2=\rho_3=1·03$ ohms. The average watts due to leakage and iron losses = 1301. Assuming that 176 watts represent the rate of dissipation of energy in the iron, we have 1,125 watts due to stray field. Take Table VII., in which the external resistances $\rho_1=\rho_2=\rho_3=0·15$ ohm. The average

rate of dissipation of energy is equal to 216 watts, leaving very little for waste field. In this experiment the magnitudes are great, and the difference we are considering is small. A small error in the value of ϵ ther magnitude will affect this difference seriously, and it has not been measured as a direct quantity. We may say that the dissipation of energy by waste field in this experiment is comparatively small if we assume that 176 watts are dissipated in the iron. Coming now to the last Table VIII., we see that iron losses and leakage account for 905 watts, leaving 729 for waste field, if we assume 176 for the iron losses. The variation of torque over a half period is shown by the figures in Tables VI., VII., and VIII.; in Table VI. the maximum and minimum values deviate from the mean by 23·3 and 2·63 per cent. In Table VII., these per centage figures are 9·5 and 11·4; and in Table VIII. they are 58·8 and 43. With a pure rotating field the torque should be constant.

Table IX. shows collected results for each of the four experiments described. The phase differences have been taken from the curves after plotting on squared paper. We notice, firstly, as a numerical quantity the leakage as between the maximum average values of the primary and secondary per half period amounts to 26·3, 23·9, 28·7 and 76·5 per cent. in the four cases. With regard to phase differences we notice that with 0·15 ohm in each armature circuit the difference between $m_1\ dI_1/dt$ and x_1 as also $m_2\ dI_2/dt$ and x_2 has its minimum value of 47°·4 (360° = 1 period). Taking the phase with ∞ in the armature as an origin, we see that $m_1\ dI_1/dt$ and $m_2\ dI_2/dt$ experience little change; but e_1 e_2 e_3 are much altered, the signs however are not altered. The phase of x_1 and x_2 has maximum diminution with 0·15 ohm; the phase of y_1 y_2 y_3 are much increased between ∞ and 0·15 ohm, but have not such a great increase between 0·15 and 0·012 ohm. The phase difference between x_1 and y_1 y_2 y_3 has a maximum value for 0·15 ohm. As is well known, the conclusion is that unlike the direct current motor an induction motor gives maximum starting torque for a particular external resistance in its armature, below or above which the torque decreases. The power factor is a maximum, since phase difference between applied potential difference and current is a minimum with maximum torque.

In applying an induction motor for the propulsion of a tramcar, for example, the controller should be so arranged that at starting the driver cannot exceed the position for maximum torque. With direct currents it happens that a careless driver puts over the controller too far at starting, with the result that the car jumps forward. With an induction motor such use of the controller would result in an abnormal current from the line, but practically no starting torque.

To give a complete account of this motor it would be necessary to observe curves for variation of frequency and potential differences, E_1 E_2, and position of armature with respect to field. The preceding curves refer to a frequency 52 and $\sqrt{\text{mean}^2}$ E_1 and $E_2=60$ volts. A similar set of curves

Digitized by Google

have been obtained at frequency 95 and $\sqrt{\text{mean}^2}=80$ volts, the position of armature with respect to field being unaltered. The results of these tests are given in Tables X., XI., XII. and XIII. It will be seen that the same character of result is obtained, namely, that as the independent variables $\rho_1=\rho_2=\rho_3$ are given values between ∞ and 0, the torque rises to a maximum at about $\rho_1=\rho_2=\rho_3=0{\cdot}15$ ohm, and then diminishes. These tests, as well as those at frequency 52, will be specially referred to in the next section on "Armature Reaction." Table XVIII. gives a few other tests at other frequencies for which no curves have been taken.

(To be concluded.)

WIRELESS TELEGRAPHY.

We reprint below an interesting letter from the pen of Prof. J. A. Fleming, which appeared in *The Times* of Monday last, the 3rd inst. The letter deals with recent developments in wireless telegraphy on the Marconi system—the only system, by the way, that has yet attained success on a commercial scale:—

During the last few days I have been permitted to make a close examination of the apparatus and methods being employed by Signor Marconi in his remarkable telegraphic experiments between South Foreland and Boulogne, and at the South Foreland lighthouse have been allowed by the inventor to make experiments and transmit messages from the station there established both to France and to the lightship on the Goodwin Sands, which is equipped for sending and receiving ether wave signals. Throughout the period of my visit messages, signals, congratulations and jokes were freely exchanged between the operators sitting on either side of the Channel, and automatically printed down in telegraphic code signals on the ordinary paper slip at the rate of 12 to 18 words a minute. Not once was there the slightest difficulty or delay in obtaining an instant reply to a signal sent. No familiarity with the subject removes the feeling of vague wonder with which one sees a telegraphic instrument merely connected with a length of 150ft. of copper wire run up the side of a flagstaff begin to draw its message out of space and print down in dot and dash on the paper tape the intelligence ferried across 30 miles of water by the mysterious ether.

The public have already been placed in possession by *The Times* and other agencies of a general description of the apparatus employed by Signor Marconi, and there is no need, therefore, to enter into technical details. Within the last few days also various scientific men have been invited to give the public the guidance of their opinions on the novelty and utility of these demonstrations. These criticisms have for the most part not been of a very helpful character. The general public are not much concerned with questions of priority or with the claims or suggestions of rival experimentalists, but they are interested in ascertaining the serious possibilities of that which has been actually achieved. Signor Marconi has never hesitated to acknowledge that he has built upon the foundations laid by others, but a vast gulf separates laboratory experiments, however ingenious, from practical large scale demonstrations conducted with all that regularity and freedom from failure which is the absolute condition of their public utility.

I cannot help thinking that the time has arrived for a little more generous appreciation by his scientific contemporaries of the fact that Signor Marconi has by minute attention to detail, and by the important addition of the long vertical air wire, translated one method of space telegraphy out of the region of uncertain delicate laboratory experiments and placed it on the same footing as regards certainty of action and ease of manipulation, so far as present results show, as any of the other methods of electric communication employing a continuous wire between the two places. This is no small achievement. The apparatus, moreover, is ridiculously simple and not costly. With the exception of the flagstaff and 150ft. of vertical wire at each end, he can place on a small kitchen table the appliances, costing not more than £100 in all, for communicating across 30 or even 100 miles of channel. With the same simple means he has placed a lightship on the Goodwins in instant communication, day and night with the South Foreland lighthouse. A touch on a key on board the lightship suffices to ring an electric bell in the room at South Foreland, 12 miles away, with the same ease and certainty with which one can summon the servant to one's bedroom at an hotel. An attendant now sleeps hard by the instruments at South Foreland. If at any moment he is awakened by the bell rung from the lightship he is able to ring up in return the Ramsgate lifeboat, and, if need be, direct it to the spot where its services are required, within a few seconds of the arrival of the call for help. In the presence of the enormous practical importance of this feat alone, and of the certainty with which communication can now be established between ship and shore without costly cable or wire, the scientific criticisms which have been launched by other inventors against Signor Marconi's methods have failed altogether in their appreciation of the practical significance of the results he has brought about.

The public, however, are not in the least interested in learning the exact meed of merit to be apportioned to various investigators in the upbuilding of this result. They do, however, want to know whether the new method of communication across the Channel established by the expenditure of a few hundred pounds will take the place to any considerable extent of submarine cables which have cost many thousands of pounds to lay and equip. They do also desire to learn what reasons, if any, will prevent every lighthouse and lightship round our coasts from being forthwith furnished with the necessary apparatus for placing it in instantaneous and secure connection with the mainland. They also hope to hear that the methods can be applied to enable ships to be able in addition to communicate instantly in case of need with shore stations. To understand how far these things can be done, and to appreciate the necessary or present limitations of the method, it is requisite to explain that each vertical wire or rod connected to a Marconi receiving or sending apparatus has a certain "sphere of influence." Signor Marconi has proved by experiment up to certain limits that the distance to which effective signalling extends varies as the square of the height of the rod. A wire 20ft. high carries the effective signal one mile, 40ft. high four miles, 80ft. 16 miles, and so on. Up to the present time he has not yet discovered any method of shielding any particular rod so as to render it responsive only to signals coming from one station and not from all others within its sphere of influence. In spite, however, of what has been said, there is no inherent impossibility in attaining this desired result. At present all signals sent from the South Foreland to France affect the receiver on board the Goodwin lightship. But this offers no difficulty. In an ordinary electric bell system in a hotel the servant recognises the room from which the signal comes by means of a simple apparatus called an indicator, and a very similar arrangement can be applied to distinguish the origin of an ether wave signal when several instruments are at work in a common region. Subsequent inventions, as also perhaps the promulgation of some necessary Board of Trade regulations for the use of the ether, will prevent official ether wave receivers from being disturbed by vagrant electric waves sent out by unauthorised persons in their neighbourhood. The practical upshot, however, of the matter is that at present if more than two stations are not established within certain regions these stations pair and pair can communicate with each other freely and regularly by means of ether wave signals sent out and received by long vertical rods or wires. No state of the atmosphere, and neither darkness nor storm, interrupts, so far as yet found, the freedom of communication.

Up to the present time none of the other systems of wireless telegraphy employing electric or magnetic agencies have been able to accomplish the same results over equal distances. Without denying that much remains yet to be attained, or that the same may not be affected in other ways, it is impossible for any one to witness the South Foreland and Boulogne experiments without coming to the conclusion that neither captious criticism nor official lethargy should stand in the way of additional opportunities being afforded for a further extension of practical experiments. Wireless telegraphy will not take the place of telegraphy with wires. Each has a special field of operations of its own, but the public have a right to ask that the fullest advantage shall be taken of that particular service which ether wave telegraphy can now render in promoting the greater safety of those at sea, and that, in view of our enormous maritime interests, this country shall not permit itself to be outraced by others in the peaceful contest to apply the outcome of scientific investigations and discoveries in every possible direction to the service of those who are obliged to face the perils of the sea. If scientific research has forged a fresh weapon with which in turn to fight Nature "red in tooth and claw," all other questions fade into insignificance in comparision with the inquiry how we can take the utmost advantage of this addition to our resources.

ELECTRICITY WORKS ACCOUNTS.

Worcester Municipal Electric Supply Works.

It is with pleasure that we are able to show, in our analysis of last year's accounts of the Worcester electric lighting undertaking, such a substantial improvement over the already very satisfactory figures for the costs of 1897. Started on Oct. 11, 1894, the year 1898 represented the fourth completed year of working. During the year, £7,104 has been expended on capital account, raising the total expenditure to £74,397, or £149 per kilowatt of generating capacity of plant installed. Owing to the non-completion of the new engine and alternator, the connecting of new consumers was not encouraged during the latter part of the year owing to the overloaded state of the station and the absence of reserve plant. However, 80 additional consumers raised the total to 355, and the equivalent number of 8 c.p. lamps from 24,146 to 27,783—an increase of 15 per cent. With an output of 474,344 units sold, the revenue was £7,154—an average from all sources of 3·62d. per unit. The average price obtained for supply was only 2·845d. per unit—a price on which consumers of electricity in Worcester are to be congratulated. As regards the costs, notwithstanding that, in consequence of the coal strike, 123 tons of coal were paid for at from 24s. to 25s. 6d. per ton, as against the contract price of 14s. 6d., the fuel costs have dropped from 0·742d. to 0·614d. per unit. Wages, and especially repairs and maintenance costs at the station, have also been reduced. On the other hand, distributing costs and management charges have risen somewhat. The net result has been that the total costs have been reduced by nearly 0·3d., and now stand at barely 2d. per unit, a figure which is well below that of the average of municipal stations of similar output.

In spite of the low revenue, the ratio of the costs to the revenue comes out at 55·1 per cent. in 1898, as compared with 65 per cent. in 1897. For these satisfactory results great credit is due to Mr. E. T. Ruthven-Murray, who was engineer at Worcester until December 31st last.

The working profit for the year was £3,210, or 4·53 per cent. of the mean capital. After a payment of £1,725 to the reserve fund and £1,946 as interest on loans, the deficit was £460.

It should be noted that there were 10 days in the year when water power was completely unavailable, owing either to flood or drought, as against 25 days in 1896.

The following table gives the number of units generated, accounted for, and sold, which were generated by steam and by water power in 1897 and in 1898 :—

Year.	Total units.	Total B. T. U.	Steam B. T. U.	Per cent.	Water B. T. U.	Per cent.
1897	Generated	559,275	298,610	53·40	260,665	46·60
	Accounted for	434,425	242,757	55·88	191,668	44·12
	Sold	429,270	240,178	55·94	189,092	44·06
1898	Generated	610,492	283,072	46·36	327,420	53·64
	Accounted for	480,524	224,301	46·68	256,223	53·32
	Sold	474,344	222,241	46·85	252,103	53·15

Another table is also appended showing the more interesting figures for the four years during which the undertaking has been working :—

Year.	No. of consumers	Equiv. 8 c.p. lamp connection.	Output units sold.	Revenue total.	Total costs.	Deficit	Total costs per unit.
1895	181	13,522	246,912	£3,254	£3,061	£1,977	2·975d.
1896	241	21,958	333,644	4,758	3,155	1,616	2·270d.
1897	291	24,712	429,270	6,292	4,097	1,475	2·290d.
1898	382	28,496	474,344	7,154	3,944	460	1·996d.

Brighton and Rottingdean Seashore Electric Tramroad Co.

The extraordinary conditions under which this line is worked invest it with an interest more than sufficient to justify our preparing an analysis of the accounts for the year 1898. It will be remembered that the line was opened in November, 1896, and is constructed on the overhead trolley system (supplied at 550 volts pressure). The track has an 18ft. gauge and is laid along the foreshore between the terminus of Mr. Volk's little line at Brighton and Rottingdean. There is an intermediate station at Ovingdean. The level of the track is slightly above low water level, but is submerged to a depth of about 14ft. at high tide. One car only is run, and this measures 50ft. over all by 22ft. wide, weighs 40 tons, and is capable of accommodating 150 passengers at a height of about 24ft. above the rails. The power station is situated at the Brighton end of the line, and current is taken from the Corporation mains at 230 volts and transformed up to the line pressure of 550 by a 60 kilowatt motor and generator set. Accumulators are also installed in the power house for regulation purposes.

At Dec. 31st last the authorised total capital stood at £35,000, out of which £24,140 had been paid up as share capital, and £5,000 had been borrowed. At the same date the expended capital had amounted to £35,792 or at the rate of £11,931 per mile of railway.

The car-mileage for the latter half year of 1898 was 2,539, and the number of passengers carried 67,422, as compared with 2,508 car-miles and 45,106 passengers in the first half of the year. In this connection it may be interesting to note that the car-mileage and the number of passengers carried during the half-year ended December 31, 1897, was respectively 2,601 and 44,282.

The revenue earned during the last completed half-year was £1,679 or 13s. 2¾d. per car-mile. To this the revenue, at 9s. 3½d., bears a ratio of 70·3 per cent. With a revenue per passenger of barely 6d., this is quite a surprising result under the conditions. Even more remarkable are the figures representing the locomotive power costs, which in the first half of 1898 was 2s. 5½d., and in the latter half 3s. 5½d., or a mean for the year of 2s. 11d. per car-mile, considering that traffic is carried on in a mean depth of 7ft. of water and that the car capacity is 150 passengers.

The gale in the latter end of 1896 was a serious set-back to the Company through the loss of capital experienced, and we are informed that, with only one car running, the facilities for dealing with the traffic in the summer months is quite inadequate, and passengers have to be refused. We are also told that since the late reduction in the charge for power to 1d. per unit after 7d. for the first hour daily, the "locomotive power" item is and will be no more than 1s. 5d. per car-mile. If this is so, there seems every reason to expect that the line will become a financial success, and we shall look forward with interest to the publication of the accounts for the next period.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared :—

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878).

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial, Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co."

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

The Electrician *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 6d.	16s. 6d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By R. Tremlett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particular on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 13s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 3d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 3d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—"The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

THE ELECTRIC ARC.—By Mrs. Ayrton. This work will shortly be published, and will contain an historical sketch of the early experiments on the electric arc, as well as the important results of recent research.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

INDUCTION MOTOR PROSPECTS.

The Paper, entitled "The Induction Motor," recently read before the Institution of Electrical Engineers, was, we think, somewhat misnamed. It should rather have been headed "The Starting of an Induction Motor," for, with the exception of a few general remarks at the commencement, it dealt exclusively with the tests made by the author on the behaviour when starting of a certain 15 H.P. motor temporarily in his possession. And interested though we were in the investigation of the properties of this machine, we confess that we should have been yet more interested in a Paper dealing more comprehensively with the whole question of the induction motor. Further, it is a pity that the machine experimented on was not a more representative one. The author tested it as a two-phase motor, though, as he stated, it was primarily designed to run as a single-phase; and in the best modern Continental and American practice a two or three-phase motor of like rating would be considerably more compact and run with a considerably smaller air gap, and consequently with much reduced leakage, which would in turn result in higher torque, power factor and efficiency.

But the fact that such a Paper has been read before the premier association of English electrical engineers, together with many no less significant indications of the mind of the practical engineering world, show that the induction motor is gradually coming to the front in this country as it has already done abroad, and it is safe to prophesy that, in the course of the next few years, many hundreds of motors of this class will be brought into service among us. The advantages of the polyphase system can no longer be overlooked in an age in which commercial competition is so keen that every improvement that makes for greater convenience and the reduction of labour has to be adopted if a business is to survive. It is true that in this country we have hitherto generally associated multiphase work with the use of abnormally high potential, and, with a lament for the scarcity of our waterfalls, have allowed the subject to fade from our thoughts; but day by day it is being made clearer that the advantages of the induction motor are no less marked in cases where a low potential

Digitized by Google

would naturally be employed. We are now speaking of bi- or tri-phase induction motors, and not of the single-phase motor, which though no doubt extremely serviceable in certain cases, yet, on the whole, lacks just those qualities of simplicity and hardiness which give the polyphase motor its pre-eminence. As compared with its continuous-current rival, the multiphase induction motor can be made at least as light, and certainly more compact, and, as there is no commutator, and in the smaller sizes no rubbing contacts whatever, it can be left quietly running in dark and unhealthy corners for weeks with no further attention than an occasional oiling and blowing free from dust. It can start itself on full load, regulate itself; in fact, look after itself entirely. In short, it may be regarded as nothing more than a metal case giving forth rotary energy. Further, it can be constructed to give as much as four or five times its full load torque at starting—an important consideration in crane or hoist work—and will, as a rule, stand an overload that would ruin the commutator of the best continuous-current motor; though, of course, such an overload must not be applied continuously, or overheating will result, as with the continuous-current motor. It is true that motors with unusually large starting torque lose somewhat in efficiency, and that the induction motor, as a whole, labours under the disadvantage of having a power factor less than unity (varying from about 90 per cent. at full load to about 60 per cent. at quarter-load), and, further, that the starting current is, say, two or three times the full load current when no variable resistance is arranged for in the rotor circuit, but these drawbacks are far more than compensated for by the advantages above mentioned. This is particularly the case with small motors, say, up to 10 or 12 H.P., where efficiency in power is of small moment as compared with ultimate efficiency in the matter of convenience. Moreover, by the addition of three rubbing contact rings on the rotor, and a suitable external resistance (such as is generally provided with motors of about 10 H.P. and upwards), the efficiency can be made quite as high as that of the corresponding continuous-current motor, and at the same time the starting current can be brought down so as not to exceed the normal full-load current while the torque is but little less than at full load. Also, by keeping the resistance in circuit and altering it while the motor is running, the speed of rotation can be varied to any desired extent, though, of course, with varied efficiency. Much has been said concerning the wastefulness of this arrangement, and the continuous-current motor has been lauded in contrast, but in how many cases in practice do we find that a stationary shunt or series continuous-current motor is regulated by alteration of the field ampere turns? Not more than in perhaps nine or ten out of a hundred; whatever regulation is required being, as a rule, obtained in exactly the same way as in the induction motor, *i.e.*, by the insertion of resistance in series with the armature. Surely, then, the advantage lies with the induction motor, which requires no automatic device to protect its armature against interruption in the supply, nor any automatic circuit breaker to guard a commutator against overload. And it should be remarked that in those comparatively few cases in which the regulation of a continuous-current motor is effected by alteration of the field ampere turns, this means that the magnets and field windings are heavier, and the machine consequently costlier than would otherwise be the case. But as often as not it is constant, and not variable, speed that is required; and here the induction motor once more scores over its opponent, for the only factor upon which its speed depends (apart from alteration of the resistance of the rotor circuit) is the frequency, which may be kept as invariable as is desired in the generating station; while, in the case of the continuous-current motor, the voltage, the load, and (in the case of a shunt machine) the temperature, of its field coils, all produce variations. It is, of course, true that the induction motor does not run quite in synchronism with the revolving field of the stator, but the slip is exceedingly small, being only about 2 per cent. at full load in a 50 or 100 H.P. motor, and but 7 per cent. in one of 2 H.P., and proportionally less at smaller loads. The pressure of supply in a polyphase system should, however, be kept as constant as possible, since the power of an induction motor varies as the square of the impressed E.M.F., and if that E.M.F. falls to any considerable extent the point of maximum torque may be but little beyond the working torque, with the result that should the load be increased the motor may suddenly pull up.

Yet there is one class of work for which the two or three-phase motor does not seem, at least at present, to be adapted, namely, for the propulsion of tramcars in an urban district where frequent changes of speed are necessary. For railways or tram lines in the country, where full speed may be maintained over long distances at a time, and where there are but few crossings, such motors are extremely suitable, not only on account of the high potential which can be employed in the transmission line, but also because of the simplicity of construction of the motors themselves. But in crowded town traffic the case is otherwise, and it is far more economical in power to employ on each car two continuous-current series-wound motors, the speeds of which are regulated by a series parallel controller. In addition to this, the continuous-current system has the advantage of requiring but a single-trolley wire, as against the two required by the polyphase, which lead to considerable complication and trouble when the crossings are numerous; even allowing for the fact that a polyphase motor will work as a single phase if once started, and that, consequently, where the lines meet, but a single trolley need be employed. There is the further objection to the polyphase trolley-wire system, that it has great inductive effects in neighbouring wires which, of course, are numerous within the limits of a town or city.

REVIEWS.

Electricity in Town and Country Houses. By PERCY E. SCRUTTON. (London: Archibald Constable and Co. 1898.)

Assuming that there is a legitimate function for books of this class, the work under present notice stands criticism perhaps better than most of such works. Some of the chapters —notably the last two or three—are somewhat loosely written, with the result that to the uninitiated, for whom the book is intended, many statements are apt to convey an erroneous impression. There is also here and there, where such is attempted, incompleteness of discussion of practical details. The author has, on the whole, very fairly suceeded in his object as defined in the opening sentence of the first chapter, which "is to put before the reader in a popular form the many uses to which electricity can be put in his house . . . and the cost which the use of it entails."

Dictionaire Technique Français-Anglais des Outils et Ustensiles Employés dans lès Métiers Manuels, La Petite Industrie le Ménage, &c. By A. S. Lovendal. (Paris: Boyveau et Chevillet, 1899.)

This is not a dictionary, but a vocabulary of tools used in various trades, and it has, therefore, limited application. The words are arranged under about 50 headings, and only in a few instances alphabetically. A draw-vice (mâchoire à tendre) is called an "electrician's stretching jaw," and, with unexpected humour, the next entry is electrician's twisting jaw —mâchoire *à tordre*.

THE HISSING OF THE ELECTRIC ARC.*

BY MRS. AYRTON.

(Concluded from page 794.)

We now pass from the consideration of the electrical measurements of the arc to the appearance of the crater, arc, and carbons. Every alteration of the current and of the distance between the carbons naturally produces a corresponding modification of all parts of the arc, but until the value of the current attains a certain magnitude, which depends only on the length of the arc with a given pair of carbons, this change is one of degree merely, and not of character. A greater current simply produces a large crater, a larger arc, and longer points to the carbons. When the special current is reached, however, a change which is no longer merely one of degree, takes place in the crater. Instead of presenting a uniformly bright surface to the eye, this becomes partly covered with what appear to be alternately bright and dark bands in one or more sets of concentric circles, moving round different centres in opposite directions. The directions of rotation and the entire positions of the images change continually, and the motion grows faster and faster as the current is increased. It is impossible that these figures, which do not move too fast to be clearly seen by the eye in an image of the arc magnified only 10 times, should have escaped the observation of all those who have made a study of the arc, and yet, after a careful search, I can find no mention of them anywhere. When the current is so much increased that the motion becomes too fast for the eye to detect, the arc begins to hum, and then, as Mr. Trotter † first showed in 1894, it rotates at the rate of from 50 to 450 revolutions per second. These rapid revolutions, which the unaided eye is incapable of observing, he discovered by the use of a disc having alternate arms and spaces, and kept in rapid rotation ; but, in his account of his observations, he makes no reference to the relatively slow rotations which *precede* the hum. In fact, the rotations observed by Mr. Trotter appear to begin just where those I have been describing become too quick for the eye to see unaided, and end just as the arc begins to hiss, for he mentions that at 450 revolutions per second the arc breaks into a hiss. As soon as hissing begins, the whole appearance of the crater changes again ; a sort of cloud seems to draw in round a part of it, moving from the outer edge inwards, and varying continually in shape and position. Sometimes but one bright spot is left, sometimes several, but always the surface is divided into bright and dull parts, giving it a mottled appearance, as is slightly indicated in (*b*) Fig. 4. If, then, the current be diminished, so that the arc becomes silent again, the whole surface of the crater grows dark for an instant, then brightens in spots and finally becomes bright again all over.

The vaporous arc itself undergoes fewer modifications ; it preserves the ordinary characteristics of the silent arc while dancing circles hold possession of the crater, but, when humming begins, a green light is seen to issue from the crater, and with hissing this becomes enlarged and intensified, till the whole centre of the purple core is occupied by a brilliant greenish-blue light, as is indicated in Fig. 5. The *shape* of the arc now alters also. While it is silent or humming, no great difference can be observed in its form. With solid carbons it is rounded or pear-shaped according to its length, and has an appearance of great stability. But as soon as hissing occurs, the arc seems to suddenly dart out from between the carbons and to become flattened out, as if under the influence of a centrifugal force acting at right angles to the common axis of the two carbons. In Fig. 5 this flattened appearance is well marked, as it is also in (*d*) Fig. 6 ; and, indeed, these figures show that every part of the vaporous arc itself is involved in this flattening—the purple core, the shadow round it, and the green aureole—as if they were all revolving with great rapidity round a common axis. And what more likely than that this is the case, since, as has already been mentioned, the arc is revolving at the rate of 450 revolutions per second *at the moment that it starts hissing*. As regards the carbons themselves, the only important modification of the *negative* carbon that appears to be due to hissing is the formation of the well-known "mushroom" at the end of that carbon with a *short* hissing arc. This mushroom, of which a good example is seen in Fig. 5, is well named, not only because of its shape, but also because of the rapidity of its growth, which is so great that while it is forming the carbons often have to be *separated*, instead of being *brought together*, to keep the length of the arc constant.

And now we come to the most important of all the changes that take place when the arc begins to hiss, viz., the alteration in the shape of the *positive* carbon. During the course of his 1889 experiments, Luggin ‡ observed that the arc hissed when the crater filled the whole of the end of the positive carbon. He was thus the first to call attention to the fact that there was a direct connection between hissing and the relation between the area of the crater and the cross-section of the tip of the positive carbon. My own observations in 1893 led to a conclusion somewhat similar to Luggin's, but yet differing in an important particular. It seemed to me that with hissing arcs the crater always *more* than covered the end of the positive carbon—that it overflowed, as it were, along the side. How far this is true will be seen from an examination of Figs. 4, 5, 6, and 7, which show the shaping of the carbons under various conditions with silent and hissing arcs. These figures have all been made from tracings of the images of actual normal arcs, burning between carbons of various sizes. For Fig. 4 the diameters of the carbons were the same, but the currents and lengths of arc were different. Fig. 5 is the image of a short hissing arc. For Fig. 6 the positive carbons were all of the same size, and the arcs of the same length, but the current had four different values, while for

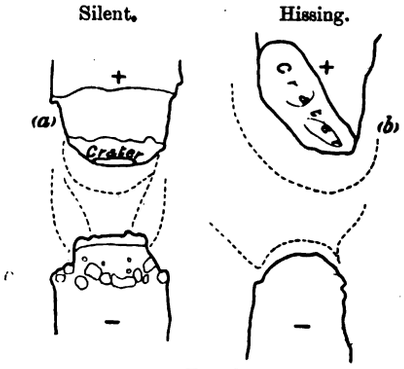

Fig. 4.

Carbons: Positive, 9mm. cored ; Negative, 8mm. solid.
Length of Arc: (*a*) 5mm. ; (*b*) 8mm. Current: (*a*) 3·5 amperes ; (*b*) 34 amperes.

Fig. 7 the current and the length of the arc were the same for both (*a*) and (*b*), but the diameter of one of the positive carbons was twice that of the other. The figures were carefully chosen with special reference to the shaping of the positive carbons. For with normal arcs the shape of the end of a positive carbon, even taken quite apart from that of the negative carbon and of the vaporous arc itself is capable of revealing almost the whole of the conditions under which the arc was burning when it was formed. It is possible, for instance, with a normal arc, to tell, from a mere drawing of the outline of the positive carbon and of its crater, whether the arc with which it was formed had been open or enclosed, short or long, silent or hissing, burning with a large or

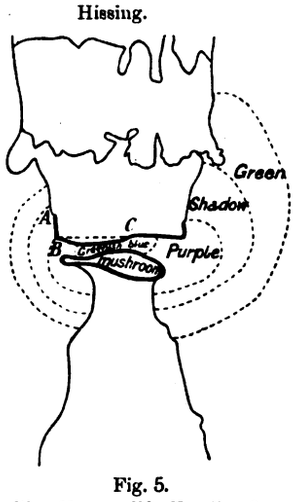

Fig. 5.

Carbons: Positive, 11mm. solid ; Negative, 9mm. solid.
Length of Arc, 1·5mm. Current, 28·5 amperes.

with a small current for the size of the carbon. Take, for example, Fig. 4, and note the difference in the shape of the positive carbon with a current of 3·5 amperes as in (*a*), and with one of 34 amperes, as in (*b*). In the first case the tip of the positive carbon is rounded, so that the crater lies in its smallest cross-section ; in the second, the tip would be practically cylindrical for some distance, but that the crater has burnt away a part of the cylinder, making the tip look as if it had been sheared off obliquely. Comparing now the tips of the positive carbons when the arc is silent and when it is hissing in all the four figures, 4, 5, 6, 7, we find the same difference. With all the silent arcs the tips are more or less rounded, and the crater lies in its smallest cross-section, and consequently is less in area than any but the smallest cross-section. With all the hissing arcs, on the other

* Paper read before the Institution of Electrical Engineers, March 23rd.
† *Proc. Roy. Soc.*, 1894, Vol. LVI., p. 262.
‡ *Wien Sitzungsberichte*, 1889, Vol. XCVIII., p. 1,192.

Digitized by Google

hand, the tip of the positive carbon is practically cylindrical for a short distance at least, or would be, but that it is sheared away by the crater; consequently, the area of the crater is *greater* than the smallest cross-section of the tip, or, indeed, than the cross-section of the tip for some little distance along its length.

We have now arrived at the real, the *crucial*, distinction between a silent and a hissing arc. When the crater occupies the *end* of the positive carbon only, the arc is *silent;* when it not only covers the end, but also extends up the *side*, the arc *hisses*. Hence, the arc must be at the *hissing point* when the smallest increase in the area of the crater will make it begin to cover the *side* of the positive carbon, and this can only be when the tip of that carbon has very nearly the same cross-section for some little distance from its end —in other words, when its sides are nearly vertical. I shall now proceed to show that the extension of the crater up the side of the positive carbon is not the *effect* but the *cause* of hissing; that, in fact, *hissing is produced by the crater becoming too large to occupy the end only of the positive carbon, and by its, therefore, extending up its side.* This seems an absurdly simple and inadequate cause to produce such complicated phenomena as those belonging to the hissing arc, but it is the true one nevertheless. Before I proceed to prove this, I will show how the laws for the largest silent currents with normal arcs, which have been already obtained from the electrical measurements, may be deduced on the above hypothesis from Figs. 6 and 7. In Fig. 6 we have a series of four normal arcs of the same length, burning between solid carbons of the same

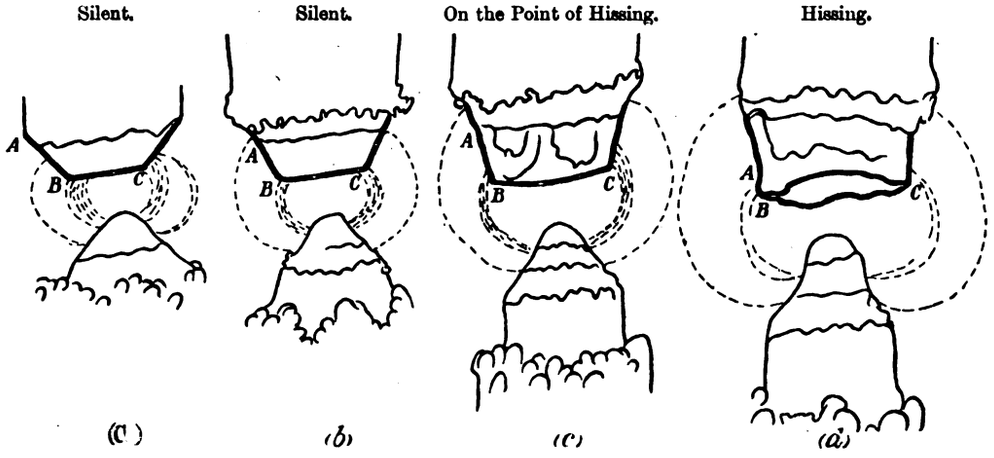

FIG. 6.

Carbons: Positive, 11mm. solid; Negative, 9mm. solid. Length of Arc, 2mm. Current: (*a*) 6 amperes; (*b*) 12 amperes; (*c*) 20 amperes; (*d*) 30 amperes.

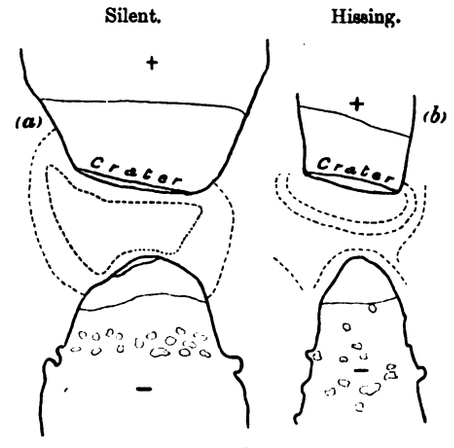

FIG. 7.

Carbons: (*a*) Positive, 18mm. cored; Negative, 15mm. solid.
(*b*) Positive, 9mm. cored; Negative, 8mm. solid.
Length of Arc, 5mm. Current, 25 amperes.

diameter, but in (*a*) the current is 6 amperes, in (*b*) 12, in (*c*) 20, and in (*d*) 30 amperes. The bluntness of the tip of the positive carbon may be measured by the obtuseness of the angle A B C. In (*a*) the tip is very blunt, and the area of the crater is certainly less than any but the smallest cross-section of that tip; therefore the arc is certainly silent. In (*b*) the tip is less blunt, but the arc is still evidently silent; in (*c*) the angle A B C is much more nearly a right angle, and it is plain that a very small increase in the area of the crater would cause it to burn up the side of the tip, therefore the arc is near the hissing point. In (*d*) the angle A B C is practically a right angle, the tip of the positive carbon is cylindrical, and the crater has evidently burnt partly up its side. Thus, keeping the length of the arc constant and gradually increasing the current must gradually bring us to a hissing point. Next, I have shown elsewhere* that with a constant current the end of the positive carbon becomes rounder and blunter, and occupies a larger portion of the entire cross-section of the carbon rod the more the carbons are separated. Hence, the longer the arc the greater must be the area of the crater, and consequently the greater must be the current, before the crater extends up the side of the positive carbon. Consequently, the longer the arc, the greater is the largest silent current. Thirdly, it follows that when the current and the length of the arc have been increased to such an extent that the tip of the positive carbon occupies the whole cross-section of the carbon rod itself no further increase in the size of the crater is possible without a part of it extending up the side of the positive carbon. Hence the largest silent current for a positive carbon of a particular diameter cannot exceed a particular value, however long the arc may be made. And lastly, similar reasoning used in conjunction with Fig. 7 tells us that the thicker the positive carbon the greater must be the largest silent current for a particular length of arc, which was one of the results deduced from the curves in Figs. 2 and 3. Consequently, the fact that

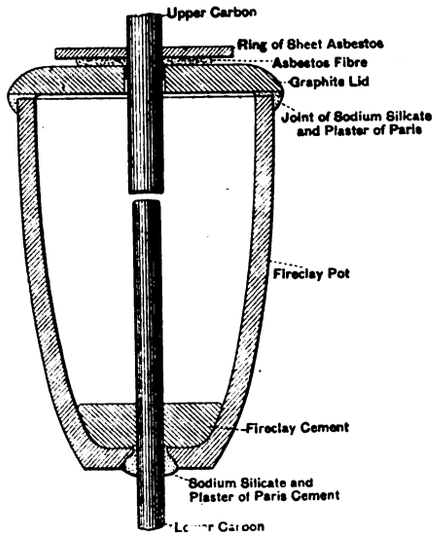

FIG. 8.

hissing occurs when the crater covers more than the end surface of the positive carbon and extends up its side, combined with our knowledge of the way in which the positive carbon shapes itself in practice, is sufficient to enable us to deduce *all* the laws already given which govern the largest current that will flow silently with the *normal* arc under given conditions. It is also now obvious why, when the arc is *not* normal, it may be made to hiss with small currents or be silent with quite large ones. For suppose, for instance, the end of the positive carbon were filed to a long, fine point,

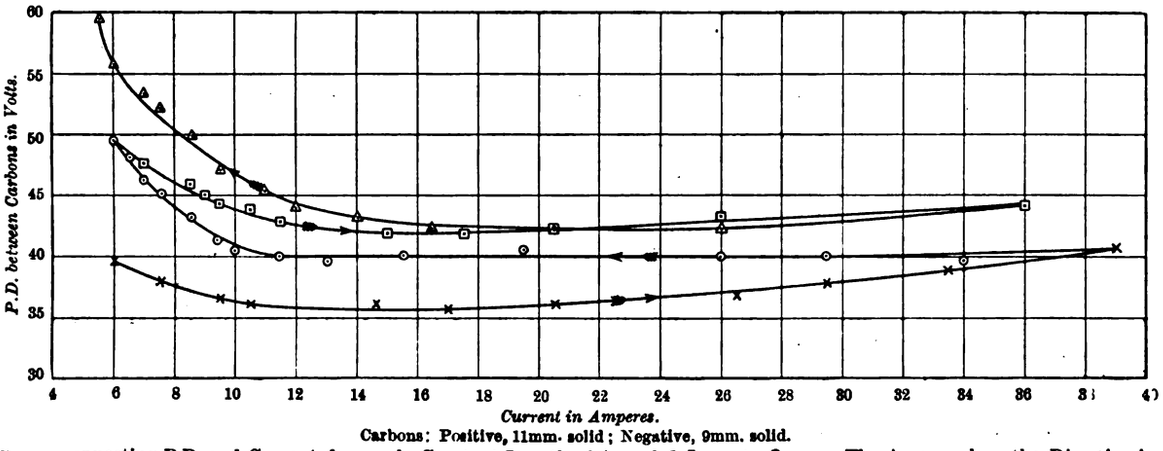
* *The Electrician*, 1895, Vol. XXXIV., p. 614.

Digitized by Google

then a very small current would make a crater large enough to extend up the side of the point, and produce a hissing arc. Whereas, on the contrary, if the end were filed flat, so as to have as large a cross-section as possible, quite a considerable current could flow silently even with a short arc, for in that case it would require the current to be great for the crater to be large enough to fill up the whole of the end of the positive carbon.

We come now to the question, why should the arc hiss when the crater burns up the side of the positive carbon—what happens then has not happened previously? In pondering over this question, the possibility occurred to me that, as long as the crater occupied only the end surface of the positive carbon, it might be protected from direct contact with the air by the carbon vapour surrounding it, but that, when the crater overlapped the side, the air could penetrate to it immediately, thus causing a part at least of its surface to *burn* instead of volatilising. Many circumstances at once seemed to combine to show that this was the true explanation. The dancing circles I had observed, and Mr. Trotter's stroboscopic images, how were they caused but by draughts getting into the arc? Then the humming noise, which I long ago described as sounding like the wind blowing through a crack, was not this probably caused by the air rushing through a slight breach in the crater already getting near to the critical size? This air, pouring in faster and faster as the breach widened, would cause the arc to rotate faster and faster, sometimes in one direction, sometimes in another, according as the draught was blown from one side or the other. Then finally the air would actually reach the crater, burn in contact with it, and the P.D. would fall and the arc would hiss. In the open arc, whether silent or hissing, the outer envelope of the vaporous portion is always bright green. With the hissing arc the light issuing from the *crater* is also bright green, or greenish blue. What so likely as that the two green lights should have a common origin, viz., the combination of carbon with air? For the outer green light is seen just at the junction of the carbons and carbon vapour with the air, and the inner one only appears when air can get direct to the crater. Again, why does the arc always hiss when it is first struck? Is it not because a certain amount of air must always cling to both carbons when they are cold, so that when the crater is first made its surface must combine with this air? The cloud that draws in round the crater when hissing begins would be a dulness caused by the air cooling the part of the crater with which it first came into contact, the bright spots being at the part where the crater and air were actually burning together. In fact, everything seemed to point to the direct contact of crater and air as being the cause, perhaps not of the hissing *sound*, but of the diminution in the P.D. betwen the two carbons, which is the hissing phenomenon.

One easy and obvious method of testing this theory immediately presented itself. If air were the cause of the hissing phenomena, exclude the air and there would be no sudden diminution of the P.D. between the carbons, however great a current might be used. Accordingly I tried maintaining arcs of different lengths in an enclosed vessel, and increasing the current up to some 40 amperes. *No* sudden diminution of the P.D. could be observed with any of the currents or lengths of arc employed, although when the same carbons were used to produce *open* arcs, the sudden diminution of 10 volts in the P.D. between the carbons occurred with a current as low as 14 amperes for a 1mm. arc. Indeed, so far from there being any sudden diminution in the P.D. when the current through an *enclosed* arc is raised to higher and higher values, the P.D. appears to slightly increase for large currents. It was, of course, impossible, in these experiments, to avail myself of an ordinary enclosed arc lamp, since a current of only some 5 or 8 amperes is all that is used with such a lamp, whereas to test my theory it was necessary to employ currents up to 40 amperes, although my carbons were of smaller diameter than those fitted in ordinary commercial enclosed arc lamps. Accordingly I constructed little electric furnaces, some made out of fire-clay crucibles with lids of graphite sealed on, as in Fig. 8; some moulded out of fire-clay with mica windows inserted, so that the image of the arc could be projected on to a screen and its length kept constant; some constructed of iron lined with asbestos. Some had tubes inserted in them through which the air could be admitted when required, &c. It was found that when the vessel was entirely enclosed, the pressure in it was so great, on the arc being first started, that occasionally the lid was blown off. Consequently the space between the positive carbon and the asbestos ring was left open till the arc was well started, and then was tightly closed. This sudden increase of pressure probably took place when the carbons were first *brought into contact*, for Mr. Seaton,* while conducting some experiments for Messrs. De la Rue and Müller, in 1879, observed that when the arc was completely enclosed the increase of pressure when the carbons were first brought into contact was far greater than could be accounted for by the rise of temperature of the gas in the vessel, and that the pressure fell, the moment the carbons were separated, almost to what it had been before contact was made. This fact was confirmed by some experiments made by Stenger,† in 1885. This first great rise of pressure may, of course, be partly caused by the gases occluded in the carbons being expelled on the current being started, but a complete investigation of this phenomenon has not, as far as I am aware, yet been made. Some curves connecting the P.D. between the carbons with the current when the arc was completely enclosed in the crucible (Fig. 8) are given in Fig. 9. The carbons were solid, the positive being 11mm. and the negative 9mm. in diameter, similar to those used with the open arc experiments (Fig. 1). As this crucible—the first one made—had no window, the length of the arc could not be kept quite constant, but the distance by which the carbons were separated was noted at the beginning of the experiment, and they were then allowed to burn away without being moved till the end, when the distance the positive carbon had to be moved in order to bring it tightly against the negative was noted. Measured in this way, the length of the arc was 1·5mm. at the beginning and 2mm. at the end of the experiment. The current was started at 6 amperes, and gradually increased to 39 amperes; then as gradually diminished to 6 amperes again, increased to 36 amperes, and diminished to 5 amperes, when the arc was extinguished. The P.D. between the carbons for a given current seems to have increased as the length of time during which the arc had been burning increased; this was undoubtedly partly due to the lengthening of the arc, but was probably also partly due to the whole of the air in the crucible having been gradually burnt up or driven out through the slag wool and the asbestos ring by the pressure of the carbon vapour. Many other sets of curves were obtained, but all with the same result, viz., that, when once the crucible had been freed from air, no sudden diminution in the P.D. could be observed on increasing the current far beyond the value at which this diminution occurred on lifting up the lid and allowing the air to have access to the arc.



Carbons: Positive, 11mm. solid; Negative, 9mm. solid.

FIG. 9.—Curves connecting P.D. and Current for nearly Constant Length of Arc of 1·5mm. to 2mm. The Arrows show the Direction in which the Current was varied.

The next thing to do was to try if an open arc could be made to hiss and the P.D. to suddenly diminish by blowing air at the crater when the current was so small that the crator remained well at the end of the positive carbon—in fact, to bring the air in contact with

Digitized by Google

the crater artificially when a much smaller current was flowing than would usually produce hissing. I first tried inserting a carbon tube in the arc and blowing through it, but this almost invariably blew the arc out. Then Mr. Phillips, one of Prof. Ayrton's assistants at the Central Technical College, suggested using a tubular positive carbon and blowing the air down it. This plan answered admirably, for when a current of 10 amperes was flowing with an arc of about 3mm., so that the arc was quite silent, each puff of air blown down through the positive carbon was followed by a hiss and the characteristic diminution of the P.D. between the carbons. With a current of 6 amperes, however, I could get no hiss, but simply blew the arc out each time, probably because, with such a small current, the arc was cooled sufficiently to be extinguished before the action could take place. Oxygen was next tried, still with the open arc, and again each puff produced a hiss and diminution of the P.D., the latter being exactly the same in amount as when air was used, namely, about 10 volts. As my idea was that the diminution of the P.D. was due to the chemical combination of air with carbon at the temperature of the crater, the fact of oxygen producing the same diminution of the P.D. as air seemed to show that nitrogen would produce no effect, and that all the effect produced by air was due to the oxygen in it. Accordingly I tried blowing nitrogen down the positive carbon of an open arc, and found that *no* change in the P.D. followed if the nitrogen was blown through gently, but that, beyond a certain pressure, the arc was blown to one side, and thus lengthened, so that the P.D. *rose*, and, if the pressure continued, the arc went out. This experiment proved two things—firstly, that it is the *oxygen* in the air that causes the diminution in the P.D. with hissing; secondly, that this diminution in the P.D. is not due to cooling, for nitrogen would cool the arc as effectually as oxygen or air. To make assurance doubly sure on this point, carbon dioxide was blown down the tubular positive carbon, with the same result as when nitrogen was used, viz., no change was produced in the P.D. between the carbons unless the pressure of the gaseous stream were large enough to blow the arc on one side, and then an increase and not a diminution in the P.D. was observed. If, however, the current was *very near* the value that made an open arc of the particular length used start hissing, blowing either nitrogen or carbon dioxide through the positive carbon sometimes started hissing; but this was due, *not* to any direct action of the stream of gas on the carbon, but to the arc being deflected by the gaseous stream and burning obliquely up the side of the carbon, and thus allowing the air to come into contact with the crater. The proof of this was that this diminution in the P.D. had the same value as if air had been employed, and that the hissing phenomena did not disappear on stopping the stream of nitrogen or of carbon dioxide. This was not the case with hydrogen, however. When that gas was blown down the positive carbon in the open air, the arc would start hissing if the current were large enough, *and stop hissing the moment the hydrogen was shut off*. Not only this, but the diminution in the P.D. had a different value from that produced by air, being only about 6·5 volts instead of 10 volts. Table IV. gives the current and the P.D. between the carbons just before the hydrogen was turned on, just after it was turned on, just before it was turned off, and just after it was turned off.

Table IV.—*Effect of Blowing Hydrogen down a Tubular Positive Carbon.*

Carbons: Positive, 11mm. tubed; Negative, 9mm. solid; length of arc, about 3mm.

P.D. between carbons in volts.				Current in amperes.
Before H. was turned on.	After H. was turned on.	Before H. was turned off.	After H was turned off.	
52·0	46	46	53·0	14
52·0	45	47	52·0	12
52·0	45	45	52·2	12
52·5	46	46	53·0	12
52·0	45	46	52·0	9

Thus, the mean diminution of P.D. accompanying the hissing caused by hydrogen being sent down the positive carbon of an arc burning in the air was about 6 6 volts, or about 3½ volts lower than when the hissing was caused by air alone.

In order to exclude all possibility of doubt as to the effect of the various gases, I repeated the experiments with the arc entirely enclosed, so that the only gases that could reach it were those blown down the tubular positive carbon. The current was distinctly below the hissing point, being only 10 or 11 amperes, and the arc was from 2mm. to 3mm. long. When air was blown down the positive carbon, each puff lowered the P.D. by about 10 volts, and the moment the puff ceased the P.D. rose again. Next, oxygen was tried, with the same result. Thirdly, nitrogen with *no* result, or with the result that the arc was blown out if the pressure was too great. Carbon dioxide had the same effect as nitrogen, and lastly hydrogen was tried. This gas, however, gave a totally different result with the enclosed arc from that already obtained with the open arc. For whereas, as has been previously stated, hydrogen produced a distinct hissing of its own when blown down the positive carbon in the *open air*, it produced *none* when used in the same way with the *enclosed* arc.

To prove that, in order to produce the sudden diminution of P.D. under discussion it was necessary for the active gas to actually touch the crater, a tubular *negative* carbon was used, and each gas was blown up through it in turn, gently enough not to force the gas directly against the crater. In *no* case was there any sudden diminution of the P.D., whatever was the gas blown through the negative carbon, and whether the arc was open or enclosed. On the contrary, there was generally a small increase, probably due to the lengthening of the arc by its being blown on one side. If oxygen or air were blown *very hard* up the negative carbon, they would either produce hissing, or blow the arc out, or both; for in that case some of the gas got to the crater uncombined with the carbon vapour, and acted exactly as if it had been blown down the tubular positive carbon. The case, then, stands thus:—(1) When the arc begins to hiss in the ordinary way, the P.D. between the carbons diminishes by about 10 volts. (2) If the air is excluded from the arc, this diminution of the P.D. does not take place, even when the current is nearly three times as great as would cause hissing in the air. (3) If, however, while the air is excluded, puffs of air are sent against the crater, the diminution of the P.D. *does* occur, even with currents much *smaller* than would cause hissing in the air. (4) If, instead of air, *oxygen* is sent against the crater, the P.D. is diminished to exactly the same extent as when air is used. (5) If, on the other hand, *nitrogen* is sent against the crater, *no* diminution of the P.D. is observable. (6) If air or oxygen is gently blown through the *negative* carbon, so that it cannot get direct to the crater, *no* diminution of the P.D. follows. Thus there can be no shadow of doubt that *the sudden diminution of P.D. that accompanies the hissing of the open arc is due to the oxygen in the air getting directly at the crater and combining with the carbon at its surface.*

This explanation, like many another in science, solves certain difficulties, only to create others which may, perhaps, be yet harder to deal with. Directly we know exactly how the diminution of P.D. accompanying hissing is brought about, we ask, "How does this combination of gas and carbon, at the temperature of the crater, act in producing a diminution of P.D. so sudden, so certain, following such definite laws as those we have been considering? Why do certain gases produce it and not others? Why does hydrogen act in the presence of air, but not when air is absent?" &c. These are questions that have been occupying me for some time past, and which will, I hope, be completely answered by the series of experiments on which I am still engaged. These latter experiments, although suggested by the investigation on the hissing of the electric arc, have already opened up a different field of inquiry, and the further results may, therefore, with advantage be reserved for a future communication.

It only remains for me to express my high sense of the honour done me by the Institution of Electrical Engineers in asking me to read this Paper, and to thank the many people to whom I am indebted for very kind assistance. My most sincere thanks are due to Prof. Ayrton for much criticism, for advice as to the methods of conducting the experiments, and for invaluable help in the literary portion of the work; to Mr. Solomon for constructing with much ingenuity the first enclosing crucible, and for making the earlier experiments with it; to Mr. Phillips for assisting in the experiments and for drawing most of the diagrams, especially the admirably executed coloured drawings of the hissing and silent arcs; to Mr. Carter for supervising, and to Messrs. Manuel and Pletts for very carefully constructing the apparatus for the experiments of this evening; and lastly, to Messrs. Arundel and Spencer for helping with most of the experiments for the Paper, and for conducting many of them alone, with great skill and patience, as well as for carrying out all those that have been shown to you this evening.

The Pan-American Exhibition.—As has already been notified, it was intended to hold a pan-American Exhibition in the coming summer on the Niagara border, but owing to the outbreak of the Spanish-American war, it was decided to postpone it until 1901. The American press is again calling attention to the scheme. The exhibition has been planned on a large scale, and its principal object is said to be the extension of trade relations between the United States and all the South American States, by forcibly bringing before the public of the former country the products of the latter. It is stated that one of the chief features of the exhibition will be the electrical exhibits, but we should imagine that, with the exception of raw india-rubber, these would be provided entirely by the countries in the northern part of the hemisphere.

PHYSICAL SOCIETY.

At an ordinary meeting, on March 24, 1899, Prof. Oliver Lodge, F.R.S., President, in the chair, Mr. W. R. COOPER read a Paper, by A. P. Trotter, on

"The Minor Variations of the Clark Cell."

The author describes a series of experiments in which he compared the E.M.F.'s of certain standard cells at frequent intervals from July, 1896, to February, 1897, at Cape Town, where the temperature of the double box containing the cells varied between the limits 13°C. and 28°C. One cell was selected for comparison with all the others. No special precautions seem to have been taken to keep the temperature of this selected cell constant. The observed differences between the E.M.F.'s of the respective cells rarely exceeded 0·001, corresponding to about a quarter of an inch on the slide-wire of the potentiometer. Details as to the area of the slider-contact are not stated; the readings were generally taken to the fourth decimal, *i.e.*, to one-tenth of a millivolt, and occasionally to one-fourth of this. Temperature was read to 0·1°C. on a mercury thermometer placed through a hole in the double box containing the cells—not in the cells themselves.

Mr. E. H. GRIFFITHS said that the Paper appeared to have value only in so far as it showed that Clark cells at Cape Town behaved in a manner that agreed with common knowledge and general experience everywhere else. Their variations depended upon shifts of temperature and the consequent changes in the degree of saturation of the liquid. From his own experiments during seven years, upon 42 Clark cells, he had shown that if temperature was kept constant to within 0·01°C., the steadiness and uniformity of all the E.M.F.'s was most remarkable. They started with discrepancies, but at the end of the time it was impossible to detect any differences. It was of little use to put a thermometer anywhere but within the cells; very slight changes of temperature caused serious changes in the degree of saturation of the liquid. The existence of the capricious lag of E.M.F. behind temperature precluded the possibility of formulating a temperature correction for Clark cells. In the case of Callendar cells there was no lag; their E.M.F. varied slightly with temperature, by a definite amount, which could be corrected by a coefficient.

Mr. W. R. COOPER said the method of comparison used by the author was unsuitable, because to arrive at the differences of E.M.F. necessitated the measurement of the E.M.F. of each cell. The variations only amounted to a few ten-thousandths of a volt. The length of potentiometer wire corresponding to a thousandth of a volt was only a quarter of an inch; under such conditions it would be difficult to ensure accuracy. A method of opposition would have been preferable. Mr. Cooper had found that Board of Trade cells only vary about one ten-thousandth of a volt between themselves from day to day. Cells of the H-form vary about one-fifth of that amount.

Prof. J. D. EVERETT then read a Paper by Dr. E. H. Barton and Mr. W. B. Morton, on

"The Criterion for the Oscillatory Discharge of a Condenser."

The object of the Paper is to inquire how the condition for the oscillatory discharge of a condenser is modified when the ordinary differential equation of the second degree is supplemented by the terms added by Maxwell to take account of the distribution of current in the (straight) wire. The co-efficients of these terms are relatively small, so that the algebraic equation giving the periods is a quadratic, with small terms of higher order added. The effect of these higher terms is, first, to introduce very rapid vibrations of small amplitude; and, next, to displace the roots of the unaltered quadratic. The nature of the discharge—oscillatory or non-oscillatory—may be taken to be determined by these principal roots, and the critical case is when they are equal. The condition for equality is obtained, by the property of the derived function, as a series of powers of the small coefficients of the equation, which may be carried to successive approximation as far as is desired. The Paper also treats the question by an alternative, and more physical, method, which consists in replacing the resistance, inductance, and capacity that occur in the ordinary formula, by modified values. This gives the criterion correct to the third order in the small terms. It is shown that a condenser satisfying the critical condition on the simple formula would, when the added terms are taken into account, give an oscillatory discharge.

Prof. LODGE said that the result naturally to be expected of "throttling," viz., the increase of resistance, and decrease of self-induction, due to the current keeping to the outside of the conductor, would tend rather to damp out the oscillations than to favour them.

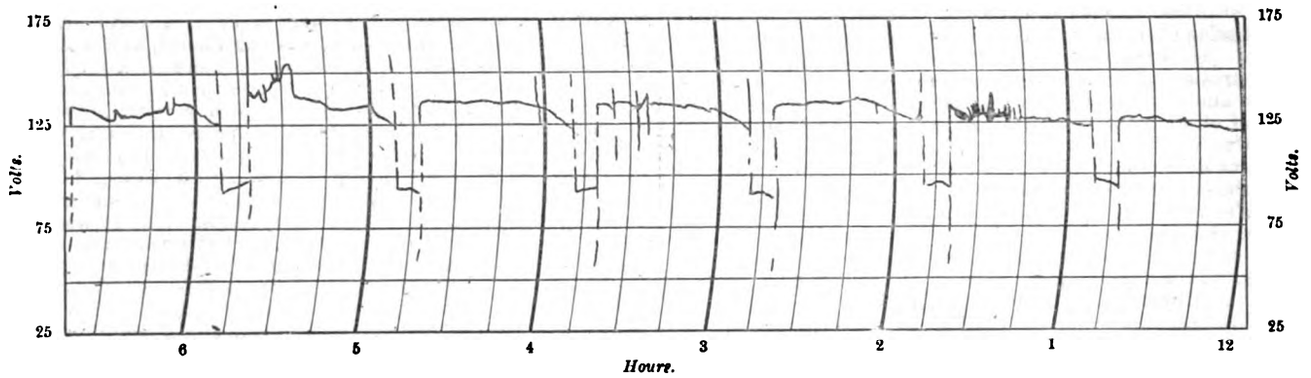
Prof. EVERETT observed that the equation was no longer a quadratic, and that the quadratic criterion as to whether the discharge was oscillatory or non-oscillatory, did not hold. The Paper appeared to be consistent with itself, and he considered that the authors had satisfactorily proved, in their discussion of the equation of current, that the effect of "throttling" was to *increase* the tendency towards the oscillatory mode of discharge.

Prof. LODGE admitted that the quadratic criterion did not hold; he thought it most likely that the authors, who evidently had gone into the matter with care, were right. At the same time, he wished to call attention to the singular and unexpected character of their conclusion. If it turned out that it was correct, *i.e.*, that there was no slip in sign, it was a result upon which he would desire to congratulate them.

The PRESIDENT proposed votes of thanks, and the meeting adjourned until April 21.

RECORDING INSTRUMENTS FOR TESTING INSULATION.

If a voltmeter be connected between any wire of an insulated two or three-wire network and earth, and then shunted by a known resistance, the insulation resistance of the network may be calculated from the two readings and the resistances of the shunt and voltmeter. Messrs. Elliott Bros. are introducing a recording voltmeter, fitted with a device patented by M. Travailleur, by means of which the instrument is automatically shunted for a short period once an hour. The voltmeter is intended to be connected between one of the switchboard 'bus bars and earth, and in this way a continuous test of the insulation resistance of the network is obtained. The recording voltmeter is of the type described in *The Electrician*, Vol. XXXVIII., p. 342, with the exception that Messrs. Elliott Bros. now replace the electromagnet by a permanent magnet. The device for switching in the shunt is merely a wheel fixed to the same clockwork train which moves the paper chart. On this wheel are pins, which at intervals of an hour close a spring contact connecting the shunt to the voltmeter. We give a reproduction of a piece of chart taken from an instrument in use at the Brussels electricity works. The resistances of the voltmeter and shunt are about 1,200 and 500 ohms respectively on 2 × 110 volt systems, and double this value for 2 × 220 volt systems.



We fear that the instrument will not have much application in this country, as the general custom is now permanently to earth the middle wire at the station. On pointing this out to Messrs. Elliott Bros., they at once described to us a registering ammeter working on the same principle as the voltmeter, but without the periodical shunting device. The instrument, being on the d'Arsonval system, is permanently shunted to a low resistance which is connected between the middle wire and earth. To protect the instrument from the effects of earths on the network, an automatic switch is fitted to it, which short-circuits the instrument if the current through it exceeds a fixed maximum value. This instrument does not, of course, afford a means of actually measuring the insulation resistance of the network, but merely records the current flowing from the middle wire to earth, thus taking the place of the ordinary non-recording ammeter usually employed for this purpose.

A NEW RESISTANCE BOX.

A radical departure in resistance box design has been made by Messrs. Gambrell Bros. in a pattern recently exhibited by them in the Royal Institution library, and now being placed on the market. The plug resistance box has proved itself eminently serviceable, and is still employed as much as ever in spite of several disadvantages, more apparent in testing-room work than in the laboratory. Chief among these is, perhaps, the necessity of keeping clean the plugs and holes, and the ebonite surface beneath the latter. The dial and similar forms of resistance boxes, which have acquired considerable popularity where celerity and accuracy are all-important, have diminished but not eliminated the errors arising through bad plug contacts, at the same time lessening the probability of a mistaken reading. The insulation difficulty remains, however. To meet this, some makers adopted the sliding or rheostat form of contact, in dial form, but it does not seem to have replaced the plug contact to any great extent in boxes of large range and for accurate work. Against the good features of the dial form of box must be set the comparatively large space taken up by the coils, necessitating for the same thicknesses of wire and the same range, a larger box than when the coils are arranged in parallel lines.

Messrs. Gambrell Bros. appear to have had all these points in view when designing their new resistance box. Fig. 1 shows the general aspect of the apparatus, with the cover removed, and Fig. 2 shows one of the rows of contacts in elevation, plan and section, half actual size. In the box illustrated the coils are arranged in five rows: thousands, hundreds, tens, units and proportional coils. Contact is made by means of the shoes D (Fig. 2), which slide over the studs C. The contact shoes slide on the rods E, held down at each end by slight springs, and by turning the handle seen at the right hand end of the box in Fig. 1 all these rods are simultaneously drawn down and clamp the contact shoes, making, therefore, in each case practically perfect contact between the stud C and the rod E. When the handle at the side is not turned, the springs are sufficient to create enough friction between the metal surfaces of the shoe and stud to keep both clean, while at the same time allowing the rods F, for drawing the shoes along, to be moved with ease. The rods F pass through ebonite brushes G, and the numbers marked on the former enable the operator to read the resistance without having access to the contacts themselves. The contacts are kept free from dust and corrosion by the cover, which is screwed permanently over the top of the box. It should be added that there is a detent under each rod, so that the operator can know, without watching the figures, when the contact shoe covers the stud. As is seen in Fig. 2, there is ample space between all the studs, so that the insulation resistance should be high. The reading is very simple, and mistake is practically impossible, as the figures appear all in line, and can be read straight off. A slight disadvantage in the particular box illustrated is that the rods for the proportional coils draw out one to either side, thus considerably increasing the room which must be allowed for the box on the testing table. The contacts for the proportional coils are also not clamped by the handle referred to, stronger springs at the ends of the slide-rod being deemed sufficient to ensure good contact. However, we understand that these slight defects are remedied in other boxes on this system.

Of course, in a piece of apparatus of this sort, a great deal depends on price and durability. It would appear, that when made in numbers, and to template, the cost of the new pattern of box should compare favourably with that of the plug type. Time only can show whether the contacts will remain efficient after continued use; from an inspection of the box, however, we can see no reasen why it should not be possible to make it as durable as other apparatus of this character. A patent has been applied for.

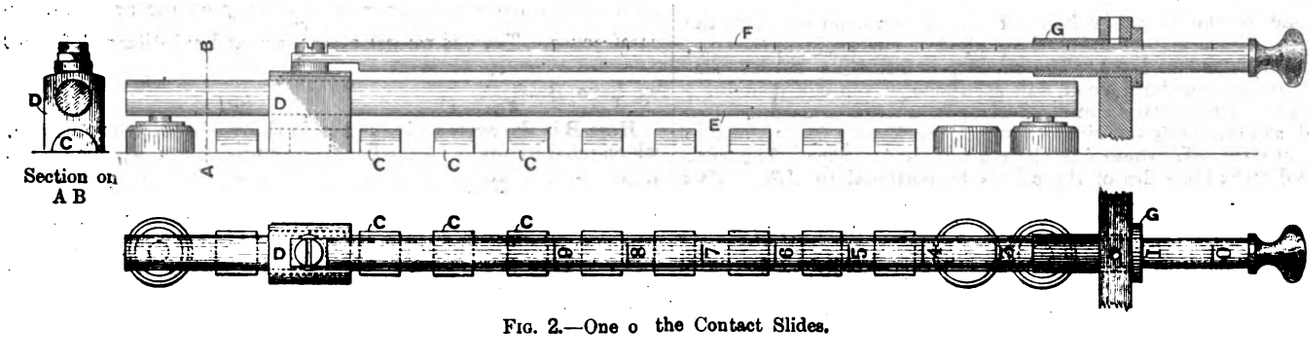

FIG. 2.—One o the Contact Slides.

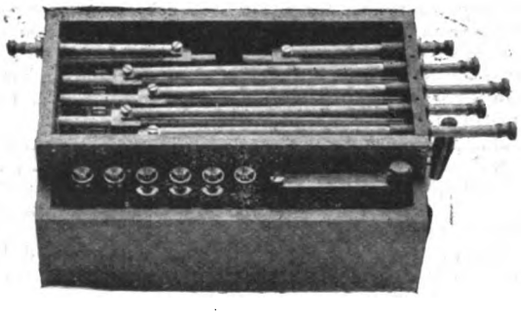

FIG. 1.—General View of Resistance Box.

THE SPARK LIMIT IN CONTINUOUS-CURRENT MACHINES.*

BY GISBERT KAPP.

Some attempts have recently been made to represent the process of current commutation in a strictly mathematical manner, taking account in the formulæ of the mutual induction of the coils, their resistance, the resistance of the constantly-changing contact surfaces between the brushes and commutator bars, &c. This manner of dealing with the subject has much interest for the mathematically inclined electrician; but the practical man will find the formulæ too complicated, as a rule, and, therefore, will not use them. He will either work quite without formulæ—*i.e.*, entirely by his experience—or he will only use such empirical rules as are favoured in his particular drawing office. The theory of sparkless commutation which I wish to develop here will occupy to a certain extent a mean position between these two methods.

One of these empirical formulæ, which has been of good service and is still extensively used to-day, consists simply in prescribing a certain maximum for the induction under the leading horn of the pole-piece—about 1,500 with drum armatures and 2,500 with ring armatures. As is the case with all empirical rules, this one can be used so long as it is applied to similar cases. It is quite possible that a rule which has no scientific foundation and is even inaccurate when looked at from the strictly mathematical standard, yet gives useful results in practice; but, then, the value does not lie in the rule, but in its limitation to definite cases. If, for instance, the rule mentioned above is only used for machines with slotted drum armatures, two armature bars per commutator segment, carbon brushes and about the same current-density with regard to the circumference of the armature, one would find that the behaviour of a machine, so far as sparking is concerned, could be predetermined with certainty. But that is no proof that it is right in general; it only proves that it is correct within particular limitations. I will now try to replace this empirical rule, which is only conditionally correct, by one which is generally followed, and to make this formula so simple that the practician is not afraid to make use of it. This latter condition can, of course, only be fulfilled at the expense of accuracy, for the process of commutation is by no means simple, and if a complicated process is to be represented by a simple formula, this formula can only be a more or less rough approximation. In addition to this, although it is desirable, it is not absolutely necessary to determine the spark limit with mathematical accuracy, for, in practice, one will endeavour to keep as far as possible from this limit. The exact knowledge of the spark limit would thus, in the first place, only have the value of allowing us to represent the safety with regard to sparking by a certain coefficient—somewhat in the way as the strength of a part of a machine can be indicated by a factor of safety. However, so long as the spark factor of safety is large enough, we do not need to trouble about its actual value. The more so as the

* Paper read before the Berlin Elektrotechnischer Verein.

Digitized by Google

sparking in a machine does not only depend upon its design, but also, to an important extent, on the manner it is used.

After these introductory remarks, which are merely intended to show the object and extent of this investigation, I will proceed to the investigation itself. Let S be the number of commutator segments, s the number of commutator segments per pole, p the number of pairs of poles, $S = s\,2p$. Let q be the number of active conductors per commutator segment (the smallest possible value of q is 1 for ring armatures, and 2 for drum armatures), $z = s2pq$ the number of active conductors counted round the whole armature circumference, n the number of commutator segments covered by one brush, L the length, and D the diameter of the armature. We will first consider the conductors belonging to one commutator segment. The current in this induces a field whose total value depends on the current volume of the chosen conductors, on the length of the armature and on the method of winding (drum or ring, smooth, slotted or hole). The conductors belonging to one commutator segment form a coil, and each side of the coil contains q wires in a ring armature and $q/2$ wires in a drum armature. The field, as induced by one side of the coil, is evidently proportional to the product iqL, where i is the current in one wire. The work stored up in the sides of the coil is proportional to q^2i^2L. This work must, by the process of commutation, first be changed into mechanical and then again into electrical work, and this by the influence of the commutating field.

If T is the period of commutation the electrical work is transformed into mechanical energy during the first half of the period, T/2. The current flows against the E.M.F. induced in the field of commutation and the coil helps to rotate the armature. During the second half of this period the current must increase from 0 to i in the direction of the induced E.M.F., *i.e.*, the coil works as a brake. Thus an exchange of work takes place between the coil and the driving machine, which can, of course, only be brought about through the action of the field of commutation. If the induction in this field is B the work put in or taken out is given by the expression

$$\int_0^{\frac{T}{2}} 2qBvLi\,dt,$$

if v is the linear velocity of the wires. B and i are functions of the time, the nature of which we cannot know exactly. We only know that B changes with the time, and that i is diminished with the time to 0, and then increases again in the opposite direction. If we confine ourselves to the second half of the period of commutation, and count the time from the moment in which $i = 0$, we can say that i and B increase with the time—the former from 0 and the latter from a determined value. If the work put in during the time T/2 is smaller than that which should be stored up in the coil, the current when the particular section is leaving the brush has not yet reached the full value i, which it must have a moment later. The coil is not yet ready to enter the armature circuit, and a spark occurs. If more work is put in than should be stored up (if B is, therefore, too large)—*i.e.*, if the current is greater than necessary, it must, when the coil enters the armature circuit, be suddenly reduced to its correct value, and a spark also occurs in this case. We see that sparkless commutation can only take place if the work put into the coil is exactly equal to that which is stored up in the coil after it has entered the armature circuit. Strictly, the work put in ought to be increased by an amount corresponding to the heating of the wires by the current and the heating at the contact surfaces of the brushes. This is small, however, compared with the electro-dynamical work, and will be neglected here in order not to complicate the calculations.

Although we are not in a position to give the nature of the functions B and i, we can still, in general, assume that the solution of the integral, by leaving out one of the numerical coefficients depending on the nature of these functions, gives for the work put in the expression qiLvT/2. Here B means the average value of the induction within the region of commutation, which must naturally be smaller than that which obtains under the leading horn, and which is given by the expression $B'_a = B_a\left(\frac{X - X_r}{X}\right)$. In this formula B_a means the induction in the air space under the poles, X the amere-turns necessary for the armature and air space, and X_r the cross ampere turns of the armature.

The work put in varies according to the law by which the current increases with time. For, under the assumption that i is proportional to t, the work will be smaller than under the assumption that the current is a sine function of the time, and that in the proportion of $\frac{1}{2}$ to $2/\pi$. But it is not necessary to make any assumption on this point, for when completing the equation between the work put in and taken out we must yet bring in an empirical coefficient. Thus we write

$$q^2i^2\mathrm{L} = \mathrm{C}qi\mathrm{L}Bv\frac{\mathrm{T}}{2}$$

$$qi = \mathrm{C}Bv\frac{\mathrm{T}}{2}.$$

Now vT/2 is the path which a side of the coil traverses during the second half of the period of commutation, that is $n\beta/2$ in which β is the distance along the armature circumference to one commutator bar. Further, $\pi D = S\beta = 2ps\beta = 2ps\frac{q}{q}\beta = \frac{z}{q}\beta$,

from which

$$\frac{n\beta}{2} = nq\frac{n\pi D}{z}\frac{1}{2}$$

$$qi = \mathrm{C}Bnq\frac{\pi D}{z}\frac{1}{2}$$

$$\frac{zi}{\pi D} = \frac{\mathrm{C}}{2}Bn.$$

zi is the whole current volume in the armature; thus zi/πD is nothing else than the linear current density on the armature circumference. Thus, if we write $\Delta = \frac{\mathrm{C}}{2}Bn$, and substitute C_e for 2/C we have $B = C_e\frac{\Delta}{n}$.

Here B is the average induction in the region of commutation, which must naturally be smaller than the induction B'_a under the leading horn. From this we have $B_a > C_0\frac{\Delta}{n}$ as a condition for sparkless commutation, in which C_0 is an empirical coefficient which depends upon the type of the armature but not upon its size or load.

As is seen this formula differs from the empirical rule mentioned at the outset only by the fact that it contains the current density and the number of commutator segments touched by the brush. We will now see if the dimensions of the formula are correct. This is the case if C_0 is actually a coefficient, *i.e.*, an unknown number. To test that, we need only answer for the values B_a and Δ according to the absolute system of measurement (M for mass, L for length and T for time). The dimensions of induction are, as is known, $M^{\frac{1}{2}}L^{-\frac{1}{2}}T^{-1}$ of current $M^{\frac{1}{2}}L^{\frac{1}{2}}T^{-1}$, and of linear current density $M^{\frac{1}{2}}L^{-\frac{1}{2}}T^{-1}$. The dimensions for linear current density and induction thus agreeing, and as n is an unknown number, C_0 must also be an unknown number. The dimensions of the formula are thus correct, but the old empirical rule incorrect, for according to this the induction must have no dimension. If, in spite of that the old rule has been of good service, this is due to the fact that Δ as well as n do not vary much in machines of the same type.

If we write out in the form of an equation

$$B'_a = C_0\frac{\Delta}{n},$$

C_0 can be considered as a sort of elastic coefficient whose value gives security against sparking. The greater the value that is chosen for C_0 in the design of a machine, or the greater value it works out to for a machine already built, the further is this machine from the spark limit, *i.e.*, the more can the machine be overloaded.

The above equation gives the necessary conditions, but not all the necessary conditions for sparkless working. One recognises that at once from the circumstance that this equation does not contain the number of armature bars per commutator segment. Now, every practical man knows that sparkless working is harder to obtain the fewer the commutator bars there are per pole, *i.e.*, the more armature bars there are to a commutator segment.

In obtaining the formula it was assumed at starting that the field of commutation, whose average value was called B, actually existed and was not appreciably distorted by the self-induced field on each side of the coil. A certain distortion is, of course, always present, but it must certainly remain small, and that is the condition for the above formula to be true. A distortion is characterised by two things—first, the strength and secondly, the space over which the self-induced field extends. So far as the strength of this field is concerned, it has already been considered in determining a formula for $B'a$. Thus we have now only to consider the space over which the field extends, and this depends, as one sees at once, on the width of the commutator bars and on the number of them which the brush covers. As this brush touches n segments, the width of the self-induced field if it were conceived to stand still in space, cannot be greater than $n\beta$. But now, on turning the armature, the field moves forward and backward by the amount β, because new segments are continually coming up under the brush on the one side, and leaving it on the other side. The extent within which a self-induced field can have a disturbing action on the field of commutation is therefore proportional to $(1+n)\beta$. In order that this oscillation of the self-induced field causes no sparks, the extent $(1+n)\beta$ must be small compared with the extent of the field commutation measured round the circumference. But the latter is proportional to the air space δ between the armature and the poles, so that, leaving out a constant, we can write for the second condition for sparkless working $\delta > \beta(1+n)$.

As is known, it is often possible to cure a machine of sparking by placing the edges of the pole somewhat obliquely with regard to the armature wires, or by planing away the edges of the pole so that the air space is somewhat greater at the leading horn. Either

Digitized by Google

means will occasion a rather larger extension of the field of commutation. If such means be adopted a value of δ must, of course, be inserted in the above expression, which is correspondingly greater than the actual distance between the armature and the middle of the polar surface. As now $S\beta = \pi D$, it also follows that

$$\delta > \frac{\pi D}{S}(1+n),$$

and by introducing the radius of the armature R and an elastic coefficient C_1, we have as the second condition for sparkless working

$$1 = C_1 \frac{\delta}{R} \frac{S}{(1+n)}.$$

The smaller C_1 is in any actual machine, the better is the machine so far as sparklessness is concerned. The condition for a machine working well is, therefore, C_0 large and C_1 small. It may now be asked how large and how small. This question can only be answered on the basis of experiment. I have determined average values for C_0 and C_1 from experiments on my own machines and from results kindly communicated to me by colleagues from trials of their machines, and I will give these presently. But now I must return to something which, in order to avoid too great complication in determining the equations, I have previously neglected, viz., the resistance between the brushes and the commutator. If this is large, a steadying action takes place, just as the well-known steadying resistance of the connecting pieces often arranged between a coil and the commutator bar. The steadying action of the resistance generally mostly influences the second condition,

$$1 = C_1 \frac{\delta}{R} \frac{S}{(1+n)},$$

because the effects of the peaks of the disturbing self-inducing field upon the field commutation are thereby lessened. Now, as carbon brushes give a greater steadying resistance than metal brushes, C_1 may be greater for the former than for the latter.

The mean values obtained for the experiments mentioned above are: —

For metal brushes	$C_1 \leqq 0{\cdot}4$
For carbon brushes	$C_1 \leqq 0{\cdot}8$
For ring armatures with smooth windings	$C_0 \geqq 12$
Ditto with slot windings	$C_0 \geqq 24$
Drum armatures with smooth windings	$C_0 \geqq 9$
Ditto with slot windings	$C_0 \geqq 15$

It is to be noticed that these values have an influence upon one another. If one finds, for instance, that in one machine C_0 is much larger than the lower limiting value comes out to, C_1 can be made larger than the upper limiting value; or if C_1 is considerably smaller than the upper limit, then C_0 can also be made smaller than the lower limit.

THE OSTEND ACCUMULATOR TRAMWAYS.

Some interesting figures relative to the cost of working a short line of electric tramways at Ostend, by means of accumulators, were furnished by the manager of the Ostend tramways, M. de Cuyper, to M. Jules Sarcia, and were embodied in a Paper recently read by the latter gentleman before the Société Internationale des Electriciens. The length of the line in question is 2½ miles, it forming part of a system of some 70 miles of tramways connecting Ostend with Blankenberghe, Nieuport, Furnes and Ypres. The generating station is situated in the main depôt and consists simply of a semi-portable non-condensing 60 H.P. engine driving a 30 kilowatt shunt Westinghouse dynamo through belting, a large hall being provided for charging the tramway batteries. The rolling stock was designed by M. de Cuyper and constructed under the direction of his assistant, M. Kamp. The truck has a wheel base of 7ft. 10½in., but, notwithstanding, can easily negotiate curves of 66ft. radius. The first batteries were supplied by the Société pour le Travail Electrique des Métaux (chloride cells), and later a Julien battery was added. The motors and controllers were supplied by the Westinghouse Co. and are of their latest pattern, the motors having laminated field magnets and steel carcases. The accumulator cars only work in Ostend during the season. At the end of 1897 M. de Cuyper was able to make the following analysis of expenditure per car kilometre:—

Coal	0·314d.
Oil and waste	0·087d.
Switchboard attendant	0·204d.
Stoker and driver (station)	0·166d.
Maintenance of batteries	0·366d.
Drivers (cars)	0·419d.
Total	1·156d.

During 1898 17,000 car miles were travelled, and the following are the items of expenditure per car mile:—

Inspectors	0·360d.
Superintendent at the charging board	0·142d.
Stoker and driver (station)	0·114d.
Maintenance of motors	0·047d.
Maintenance and repair of batteries	0·171d.
Drivers (cars)	0·408d.
Pointsmen and track-cleaners	0·190d.
Fuel	0·346d.
Oil	0·066d.
Waste	0·015d.
Total	1·859d.

To compare this figure with those customarily given for electric traction, the 0·36d., for the inspector, and the 0·19d. for the pointsmen and scavengers, should be deducted, when the total will be 1·309d. No account is taken of the renewal of battery plates, as no renewals have yet been made, the plates still being in good working condition. M. De Cuyper intends, however, to repaste the positive plates this winter ready for next season. The negative plates are as good now as they were on starting. No repair was needed to the Julien battery during 1898. Experiments made to determine the efficiency of the cars, gave on the level a mean of 552 watt-hours per car mile. The fuel consumption (briquettes) during 1898 averaged 7·11lbs. per car mile.

A tramway on similar lines has been put down at Ghent. Here there are 25 miles of track, on which 35 accumulator cars run. The mean consumption per car mile at the switchboard during the last two seasons has been 1,045 watt-hours, and the coal consumption about 6½ lbs. per car mile or per kilowatt hour.

If managers of larger lines of tramways would publish as detailed statements of costs as M. De Cuyper has done it would serve a very useful purpose.

CORRESPONDENCE.

GOVERNMENT TELEPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Permit me to notice some statements in your issues of the 17th and 24th inst. In the former you printed a letter from me quoting a correspondent, who stated that there were from 1,500 to 2,000 telephone exchanges in operation in the United States with rates varying from $1.50 to $3 a month according to the size of the town. In commenting on this you say that a comparison of the telephone areas would show as a rule that rates in America are higher than in this country. If you have evidence in support of your statement, by all means produce it, but if not, then it is mere surmise. My correspondent is engaged in the business, and, therefore, spoke at first hand. Excepting in a few leading cities where the Bell Telephone Company have still a monopoly, telephone rates in the United States are lower than here, and the service is usually good. But even in some large cities the rates are lower in the United States. For example, in Baltimore the rate is $78 – say, £16—for unlimited service within two miles of the Exchange, which is, I believe, lower than any two-mile radius in any of our towns as large as Baltimore.

We now suffer from the maintenance of rates since the patents expired by the Post Office officials in defiance of the public interest. But when monopoly is swept away we shall have service cheaper than in the United States, because materials are rather cheaper with us, and labour, which is a most important part of the cost of erecting and working telephone exchanges, averages nearly twice as much as it does here.

In your issue of the 24th inst., in noticing the Parliamentary paper just issued relating to Telephone Service in Foreign Countries, in referring to Consul-General Sanderson's letter accompanying the New York report, you say that he does not speak of municipal corruption defeating efforts for cheapness, to which I referred in my letter of the 15th inst. Consul Sanderson would do nothing of the kind. No representative of this country would, in a report in reply to specific questions, make any statements reflecting on the authorities of the place to which he was accredited. But he refers to "the fact that efforts have been made from time to time to enact legislation reducing the charges for telephone service in New

Digitized by Google

York." You add that you do not "see how the municipalities of this country would escape similar insinuations with just as much foundation"—a most unfair statement regarding our municipalities. My statements were not insinuations; they were brought before Committees of the New York State Legislature at Albany, in connection with the Bills introduced to limit telephone charges, referred to by Mr. Consul-General Sanderson. Mr. Sterne, who represented the New York Board of Trade and Transportation and other mercantile bodies of New York, in addressing the Senate Committee on February 19, 1895, referred to the reason of the enormous increase in telephone charges in New York. The service when first commenced was $5, but now they charge as high as $20 a month. This was brought about by obtaining a monopoly of underground routes, and in reference to this Mr. Sterne said, in reply to counsel representing the Telephone Company:—

"He speaks of the wires underground, and they are a great swindle. I speak advisedly. I cannot put my fingers upon the men who reap the profits of that system, but you have not far to seek outside the chiefs of Tammany Hall and various other political organisations to find out who reap the advantages of this underground system."

Why telephone service is dear in New York is, I may say, common knowledge, and the above references place within your reach the power to obtain all the information you desire on the subject. So oppressive has the monopoly been in the United States that Government has in some cases stepped in and fixed the rate at which service is supplied.—Yours, &c.,

A. D. Provand.

2, Whitehall Court, London, S.W., March 29, 1899.

THE NERNST LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I have read with much interest Mr. Swinburne's paper and your editorial comments upon it concerning the Nernst lamp. I cannot at all assent to Mr. Swinburne's statement that he has not been too sanguine. It seems to me that the lamp, although a beautiful possibility, is not yet a realised commercial factor, and perhaps never will be. Prof. Nernst is not the first to announce the principle upon which the lamp is constructed. In 1885 Mr. Jean Van Gestel and a Mr. Charles F. Beck, of Paris, were working in an analogous line, and availed themselves of the same properties of bodies which at ordinary temperatures were insulators, but at incandescence or thereabouts became conductors. Mr. Van Gestel is the well-known engineer who first described the eruption of Krakatoa, which occurred a few years ago, and which was followed by a tidal wave of which he was, perhaps, the only surviving witness. These gentlemen used plates of kaolin, which has much the same properties as oxide of magnesium, for this purpose. They employed the arc as a heating agent, with arrangements by which, when the kaolin or other electrolyte had reached its critical incandescing temperature, the main path of the current should be through it. The results are summarized in two United States patents, Nos. 322,024 and 322,033, of July 14, 1885.

Further, oxide of magnesium itself was used in the so-called "Sun Lamp," which was, I think, exhibited in London in about 1889, at an electrical exposition. At any rate, the lamp was well known at about that time. In this also the arc played over the face of a block of magnesia, which was raised to incandescence and then became the main current conductor. Air was partially excluded, and this I believe to have been the main difference between this lamp and the Nernst device; of course, I mean difference in principle.

I have witnessed a large number of tests of the Nernst lamp, and also had reports of others, amounting in all to many hundreds. In fact, three experts, not of such eminence, perhaps, as Mr. Swinburne, but certainly capable electricians and accurate observers, whose entire time is taken up with incandescent lamp experiments, worked on this lamp for many weeks, and finally abandoned it as absolutely impracticable for ordinary commercial purposes.

Mr. Swinburne says that the limiting resistance necessary is ten or twelve per cent. of that of the entire lamp. I suppose, although he does not say so, that this means 10 or 12 per cent. of the hot resistance. It was found necessary to use a limiting resistance many times this in order to secure any respectable results. The reason for this perhaps the following diagrams will make clear:—In Fig. 1, A is the resistance curve of the carbon as the temperature rises; B is the corresponding current curve. In Fig. 2, C is the resistance curve of an electrolyte, such as magnesia, and D is the corresponding current curve. It will be seen that, as the carbon gets hot, the resistance rises, and this tends to a finite value of current. In Fig. 2, however, as the electrolyte heats, the resistance falls, and the current curve diverges from it at once. The limit is removed to infinity. Of course, these are very rough diagrams, and only represent the phenomena in a general way. They do not, for instance, take into account the radiation, which very much modifies the curves.

Further, as you say in your editorial comments, Mr. Swinburne's neglect of the continuous-current side of this lamp is quite significant. In the experiments which I have named it was impossible to get any efficiency or life with continuous current; the candle-power ran down so rapidly that it was found useless to continue the experiments. Perhaps, in view of the apparent obsolescence of continuous current, or rather, the prospect of that occurring in the near future, this may not be so important as it otherwise would be.

One singular property of the Nernst lamp is not alluded to by Mr. Swinburne; perhaps he did not observe it, although it is probable that he did. Its candle-power is enough to deceive the very elect. Persons looking at it and at its apparent illuminating power upon the walls of a room, &c., made the wildest and most extravagant guesses at the photometer readings. I know that, although I had had considerable experience with the photometer, both in gas and incandescent work,

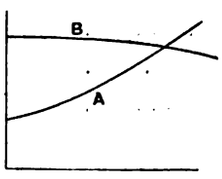

Fig. 1.

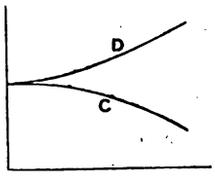

Fig. 2.

I guessed 15 c.p. when the lamp was giving three. I heard one gentleman of more experience than myself guess 32 when the photometer reading was five, and another thought it was eight when the reading was only three-fourths of one. Why this is so I cannot pretend to say.

I must dissent from Mr. Swinburne in thinking that there is no difference between luminescence and incandescence. It seems to me that this would mean that the same temperature would produce the same effect on all substances whatsoever. This is manifestly untrue at those temperatures which we can study. Hydrogen gas, for instance, takes a temperature almost inconceivable, and one certainly not attained by human means, to become luminescent; and white-hot iron is both incandescent and luminescent at what are to experimenters quite moderate temperatures.

Perhaps some of your other readers will be able to report on the Nernst lamp. It is never safe to say that any invention—so new and radical as that of Prof. Nernst—cannot be developed. I remember very well the ridicule with which Mr. Edison was met when he announced his plans for the use of the constant-potential systems now rapidly driving out everything else, and perhaps Prof. Nernst's lamp may become the incandescent lamp of the future; but I should judge that we need something better than spirit lamps and matches for an igniter, and something less than 500 volts pressure, before it will become commercial.

Is not Mr. Swinburne quite too pessimistic about the condition of the incandescent lamp in the old country? In the States we have developed quite a little in the last 15 years; we have not only cut the price into many minute fragments of what it used to be, but we make lamps which have enor-

Digitized by Google

mously longer life and better performance; so much so that the idea of replacing a part of a lamp is to the average station man quite preposterous—it is cheaper in every way to replace the whole lamp than to handle it. We have been led to infer that substantially the same progress had been made in Europe, but from Mr. Swinburne's article this seems to be a mistake. —Yours, &c., T. J. JOHNSTON.

Schenectady, N.Y., March 21, 1899.

THE WEHNELT INTERRUPTER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Among the many letters you have published with reference to the new Wehnelt interrupter, little or no mention has been made of a form which has been found of great utility, here, *i.e.*, the multipolar interrupter, in which there are a number of fine platinum wire anodes with a common lead cathode. The dimensions of the one, which has been working with great success for the last three weeks here, are as follows:—The cathode was formed by the box itself, as first used, I believe, by Mr. Swinton, and was 8in. long by 3in. wide by 6in. deep, being made of lead. The anodes, six in number, were made of 18mil platinum wire, fused into glass tubes, and projected about $\frac{1}{20}$th of an inch from the ends of the tubes. As, however, considerable difficulty was caused by the breaking of the glass, it was found that the best plan was to fit an ebonite plug into the end of the tube into which the wire was tightly jammed; the whole tube was then filled up with soft wax. These have only been in use for a little over a week, so that they have not yet received a very severe test. Mercury has been discarded from the very first for making the connection of the platinum anode with the battery, the platinum wire being silver-soldered on to a copper wire connected to a terminal on the base of the instrument.

Using this form of interrupter with a 10in. Apps coil, it was possible to so regulate the current that the coil could be used to illuminate the most delicate helium or argon tube, or to give the now well known flaming arc 6in. or 7in. long.

The great difficulty is the rapidity with which the interrupter "fatigues." This has been found to be almost entirely due to heating, since, after ten minutes run at full power, the acid got quite hot and the instrument refused to work. A new one, with a larger reservoir for acid, is now being made in which it is hoped this difficulty will be overcome. By using a variable resistance in series with the above described interrupter, it was possible to get a very large range of current through the primary of the induction coil. Using the instrument on a 50-volt circuit the actual range was from less than 1 up to 25 amperes. It need hardly be stated that the great advantage of the multipolar instrument, as a regulator, was that a small current could be sent through the primary of the coil at a high frequency, while, by simply increasing the resistance in series, the frequency diminished with the R.M.S. current.

In confirmation of the theory of resonance given by Prof. S. P. Thompson, in your issue of the 16th inst., it has been noticed that with a considerable resistance in series with the instrument, it was possible to stop the intermittent discharge by increasing the number of anodes, *i.e.*, by increasing the capacity, and very slightly diminishing the resistance of the circuit, exactly as can be done with a Leyden jar discharge. When there was no resistance in series this could not be done, since the resistance was diminished approximately in the same ratio as the capacity was increased (by increasing the number of anodes); again, in accord with the theory of the Leyden jar discharge.

With one of the original instruments made in the laboratory with a single anode of thick (about $\frac{1}{16}$in. diameter) platinum wire used in connection with an 18in. coil and a suitable X-ray tube, illumination of almost dazzling brilliancy was obtained on the fluorescent screen, while the tissues of the body showed almost as clearly as when a 16 plate Wimshurst machine was used to excite the tube, and with the same steadiness in the glow.

With this interrupter a photograph of the characteristic quartet of the blue (4,800) cadmium line under the influence of a magnetic field (viewed across the lines of force) was obtained with an exposure of only three minutes.

Trusting that I have not trespassed too much on your space.—Yours, &c., E. W. MARCHANT.

Blythswood Laboratory, Renfrew, N.B., March 28, 1899.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: This valuable device appears to possess, in addition to its power of making a continuous-current oscillatory or intermittent, the in many cases even more useful property of converting an alternating current into one which is unidirectional.

An ordinary coil supplied from mains at a frequency of either 50 or 100 alternations per second gives only the short hot flaming arc, but with the Wehnelt interrupter in primary circuit it can be made to give either this kind of discharge, or the long, crackling, multiple sparks so very characteristic of continuous-current working with a good contact-breaker.

A vacuum tube of suitable length and degree of exhaustion is invaluable as a guide to the nature of a discharge, and with such a tube of low resistance giving striæ, the discharge is oscillatory on closed circuit, but with an air spark of suitable length, it can be made more and more unidirectional, until with exact adjustment it becomes apparently entirely so. The length of air-spark required depends on circumstances, such as the resistance and form of tube.

An X-ray tube works excellently, and the arrangement promises to be a great boon to workers who have only access to alternating-current mains.—Yours, &c.,

Leicester, March 18, 1899. E. E. BROOKS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In my communication which appeared in *The Electrician* of March 24, p. 766, occurs the passage:—"Without risk of burning the contacts, notably, as is the case when one terminal alone is constantly in circuit (by the magnetic make and break)." The word "terminal" may be somewhat obscure here: and the passage might have been:—"Without risk of burning the contacts, notably as is the case when one and the same pair of metallic interfaces is always concerned in breaking contact."

One object of the idea suggested was manifestly that one of these metallic interfaces should be perpetually changed by mechanical means; which conduces to a cooling effect at the point of interruption of the current, besides allowing rate of interruption to be accurately measured and adjusted for research purposes.—Yours, &c., S. TOLVER PRESTON.

March 29, 1899.

ROTATORY CONVERTERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the February issue of the *Journal* of the Institution of Electrical Engineers Prof. Thompson replies to my contribution to the discussion on his Paper, and, as his reply constitutes the termination of the discussion—so far as the Institution is concerned—I should like to give the reply which I think his remarks on my contribution (see *Journal*, pp. 736-7) call for, through your columns.

In the first place, Prof. Thompson correctly supposes that I refer to *single*-phase, and not to *two*-phase converters, in the first part of my remarks. I am at a loss to understand how this mistake occurred.

I entirely repudiate Prof. Thompson's charge that there is confusion between angular velocity and angular acceleration in my arguments. Prof. Thompson overlooks the fact that I was wishing to show the importance of the moment of inertia of the rotating part of the converter, and that for the purpose of my argument I show what would be the result if inertia were a negligible quantity (or zero), just as Prof. Thompson has treated resistance as a negligible quantity in his Paper.

Digitized by Google

It is quite clear that if a single-phase alternate-current armature were entirely without inertia it could not run as a motor. If started it would move through an angle corresponding to half a phase, and stop when the current reached the zero point; in other words, "the angular velocity of the armature would vary between zero and a maximum.

On the other hand, if we suppose a converter entirely without inertia, and suppose it driven from the continuous side, and delivering an alternate current, the energy intake would correspond through any infinitesimal period with the energy output plus the losses, and the driving current would undulate —in the case of single phase—substantially in the manner shown in my diagrams (pp. 780 and 781).

I do not dispute the utility of Prof. Thompson's mode of determining the current distribution, *i.e.*, by superimposition, but I show that its results are not accurate, and that the truth lies between the results obtained in this way and those obtained when the result of conceiving moment of inertia negligibly small is taken into consideration.—Yours, &c.,

Nuremberg, March 26, 1899. W. B. Sayers.

AMERICAN NOTES.

New York, *March 17.*

Electric Traction.—The great event in electrical affairs is the decision of the Manhattan Railway Company to equip the Manhattan elevated roads of this city for electric power. Connected with this are repeated rumours of the consolidation of the Metropolitan and Third Avenue street railway surface systems. Another item of importance going the rounds is that all the Brooklyn surface trolley roads and the complex elevated system are to be consolidated. Consolidation is in the air. The rush of capital into combinations in the various industries since Jan. 1 was computed this week to be not far from one thousand million dollars. A syndicate with a capital stock of $25,000,000 has secured control of a large system of electric roads in the territory within a radius of 80 miles of Niagara Falls. A dozen valuable properties lose their individuality. The Philadelphia United Gas Improvement Co., capital $20,000,000, has secured control of a number of electric lighting plants in Northern New Jersey. A company with a capital of $4,000,000 is negotiating for the purchase of the street railways in six prosperous manufacturing towns in Eastern Massachusetts.

Telephony.—Independent telephone companies have been springing up fast, and the growth of these concerns has now reached a point where central organisation is possible. The Massachusetts Telephone and Telegraph Co. are taking steps to build lines throughout the New England States and to New York and Philadelphia, where they expect to do a big business. The Bell Co. is threatening to obstruct. The movement has already assumed quite formidable proportions in Michigan, where there are 26,000 independent telephones. The long-distance toll lines are of copper throughout. There is growing opposition to the high cost of the telephone service. A Bill is before the New York legislature to restrict charges. Three State officers are to act as arbitrators for the consideration of complaints.

Aluminium.—An aluminium line is about to be used in California to carry electrical power 80 miles.

Electric Rock Drill.—The first electric rock drill used in Australia has been installed by Messrs. Siemens Bros. at the Labrador Tin Mine, East Coast, Tasmania, and up to the present, according to the *Australian Mining Standard*, has given every satisfaction. The drill, which takes 1 H.P. to work it, is driven off a Siemens dynamo having an output of 30 amperes at 110 volts. This dynamo, which is also used for lighting the mine in question, is driven by a small Pelton wheel. The drill itself is a purely mechanical drill, operated by means of an ordinary small continuous-current electric motor.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

NOW READY.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s, post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s. *New edition ready May 1, 1899.*

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"Electromagnetic Theory."—By Oliver Heaviside *Vol. I.*, 12s. 6d. *Vol. II. ready May 1, 1899.*

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s. 6d.; post free, 1s. 9d.

"The Bibliography of X-Ray Literature and Research, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of general as well as special information bearing upon the whole subject of electrical discharge research. Price 5s., post free; abroad, 5s. 3d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book, by Messrs. W Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 3d. each, post free.

"The Potentiometer and its Adjuncts": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s. post free; abroad, 6s. 6d. Digest post free.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

Digitized by Google

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

IN THE PRESS.

"THE ELECTRIC ARC."—By Mrs. Ayrton.

"THE MANUFACTURE OF CARBONS FOR ALL ELECTRICAL PURPOSES."—By Francis Jehl.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside. *Vol. II. ready May 1, 1899.*

"SECONDARY BATTERIES, THEIR DESIGN AND MANUFACTURE."—By E. J. Wade.

"PRIMARY BATTERIES: THEIR CONSTRUCTION AND USE."—By W. R Cooper.

"PRACTICAL TELEPHONY."—By Dane Sinclair and F. C. Raphael.

"'THE ELECTRICIAN' WIREMAN'S POCKET-BOOK."—By F. C. Raphael.

"The Electrician" Electrical Trades' Directory and Handbook for 1899.—The "Big Blue Book" for 1899 is NOW READY. The Directory Division has been corrected up to Feb. 8, 1899, and all the latest new names, changes of address, &c., will be found included. The Handbook Division has been much extended, many valuable tables having been added. The volume contains, also, the large Sheet Tables of Electricity Supply Stations and Electric Railways and Tramways, finally corrected to Feb. 9, 1899. The price of the Directory and Handbook remains the same—10s., post free 10s. 9d.; abroad, post free, 12s. (United States 13s. 6d.).

TENDERS INVITED.

As advertised elsewhere, the *Epsom* District Council invite tenders for the supply and erection of: (*a*) Lancashire boilers and fittings, economiser, feed pumps, &c.; (*b*) pipework, &c., in engine and boiler house; (*c*) steam dynamos and motor boosters; (*d*) storage batteries; (*e*) main switchboard and connections; (*f*) overhead travelling crane; (*g*) underground mains and conduits; (*h*) arc lamps and posts; (*i*) street glow lamps and accessories; and (*k*) station lighting. Specifications, &c., may be obtained from the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C., on and after the 10th inst. Tenders to the clerk (Mr. E. G. Wilson), High-street, Epsom, by noon of May 8.

The *Hamps'ead* (London) Vestry invite tenders for the supply of two 500-kilowatt steam alternators, five Ferranti or similar type switchboard panels, boilers, feed-water heaters, feed pumps, a 40-kilowatt exciter, water softening plant, air pump and condenser, economiser, overhead travelling crane, &c. Further particulars are set out in an advertisement, and specifications, &c., may be obtained at the office of the clerk (Mr. Arthur P. Johnson), Vestry Hall, Hampstead, N.W., where tenders must be lodged by noon of May 18.

The Electric Light committee of the county borough of *Belfast* invite tenders for the supply and erection of mechanical stokers, economisers, pipe work and condensing plant. Specifications, &c., may be obtained from the city electrical engineer (Mr. Victor A. H. M'Cowen). Further particulars are given in an advertisement, and tenders must be sent in to the town clerk (Sir Samuel Black) by noon of Thursday, April 20.

As advertised elsewhere, the *West Ham* Council invite tenders for two 1,500 I.H.P. engines, two 800 kilowatt alternators and exciters, or two steam alternators and exciters. Specifications, &c., may be obtained at the borough electrical engineer's office, Abbey Mills, West Ham, on and after the 31st inst. Tenders must be sent to the town clerk (Mr. Fred. E. Hilleary) by 4 p.m. of Tuesday, April 25.

The Gas and Electricity committee of the *Stockport* Corporation require tenders for the supply and erection of a storage battery of 750 ampere hours' capacity. Specifications may be obtained from the engineer (Mr. S. Meunier), gas and electricity works, and tenders (addressed to the chairman) must be delivered by 19th inst. See advertisement.

The Town Council of *Reigate*, Surrey, require tenders for (1) two watertube boilers, economiser, brickwork, and flues, (2) steam exhaust and other pipes, steam pumps, &c., (3) two 100 kilowatt and one 20 kilowatt steam alternator, 8-ton overhead travelling crane, and sub-station equipment, (4) switchboard and instruments, (5) mains, lamp-posts, lamps and fittings. Specifications, &c., can be obtained from Mr. F. Hastings Medhurst, consulting engineer to the Council, 13, Victoria-street, London, S.W., on and after April 10, and sealed tenders must be delivered to the town clerk (Mr. Clair J. Grece), 84, Station-road, Redhill, Surrey, not later than noon of Monday, May 1. An advertisement on another page gives further particulars.

The *Bradford* Corporation invite tenders for the supply of a complete battery and switchboard for their electricity supply station, Bolton-road. Tenders to town clerk (Mr. George McGuire), by April 12.

The *London* County Council require tenders for the supply of engineers' goods and electrical stores. Tenders to Spring Gardens, S.W., by 10 a.m. 24th inst.

The *South Shields* Corporation require tenders for steam and water pipes and valves and a 15-ton hand-power overhead travelling crane. Tenders to town clerk by 20th inst.

The *St. Helens* Electricity and Tramways committee require tenders for constructing about six miles of tramways. Tenders to chairman by 19th inst.

The Corporation of *West Hartlepool* invite offers from firms or companies for "free" wiring of premises in the district. Offers to the town clerk by April 15.

The *Bristol* Electrical committee require tenders for high-tension switchboards, instruments, &c. Tenders by April 10.

The *Poplar* (London) District Board of Works invite tenders for engine and pump room equipment and all electrical plant except battery; boiler house equipment; battery and battery stands; and public street lighting. Tenders to Mr. Potts by 10 a.m. April 25.

The *Tynemouth* Corporation invite tenders for boilers, &c., economisers and fittings, ejector-condenser, circulating pumps, tanks and pipework and water cooler, pumps, feed pipes, &c., travelling crane, traction switchboard, lighting switchboard, accumulators, cables, and traction steam dynamo. Tenders to the town clerk by noon of April 15.

The Great Northern Railway Co. (Ireland) invite tenders for cables for feeders, returns, potential lines, &c., 6 motor and 6 trailer cars, overhead construction, and battery and booster. Tenders to secretary by April 20.

The Guardians of the Poor of *Rochdale* Union require tenders for a complete electric light installation at the workhouse buildings and cottage homes. Tenders to Mr. R. A. Leach, clerk, Union Offices, Townhead, Rochdale, by April 12.

The *Peterborough* Corporation invite tenders for the supply and erection of Lancashire boilers and economiser; steam dynamos, balancers and boosters; secondary battery and accessories; switchboard and instruments; piping, tank, condensers and pumps; and insulated cables. Tenders to town clerk by April 20.

The *Hull* School Board invite estimates for the installation of the electric light at the central higher-grade school and school of science. Tenders to clerk by 25th inst.

The *Edinburgh* Corporation invite tenders for installing the electric light at the City Chambers (extension buildings). Tenders to town clerk by April 10.

TENDERS RECEIVED AND ACCEPTED.

The Aberdeen Corporation have accepted the tender of Messrs. John M'Adam and Sons to construct the permanent way in connection with the electrical equipment of the George-street and Woodside tramways route, at £19,000. For the other sections of the contract, including overhead line construction, feeder, pilot, and test cables, tramway cars and accessories, and switchboard, instruments, &c, the final selection of tenders will be made by a sub-committee from the following firms:—R. W. Blackwell and Co., the British Thomson-Houston Co.; Macartney, McElroy and Co., and the Westinghouse Co. The whole undertaking is estimated to cost £35,000, and it is anticipated that the electric cars will be in operation about the end of August.

The Shoreditch (London) Vestry have accepted the following tenders for the supply of stores for the lighting department during the year:—

Crompton and Co., carbons.
Edison and Swan Company, incandescent lamps and arc globes.
Williamson and Joseph, switches, ceiling roses, and cut-outs.
General Electric Co., rubber tapes.
Johnson and Phillips, fuse and lead wires.
Pryke and Palmer, ironmongery and tools.
T. Tilley and Sons, street lamps and cradles.
G. Braulik, shades, flexible wires, and insulating materials.

The Shoreditch (London) Vestry have received the following tenders for the construction and erection of a new battery switch panel:—

Nalder Bros. and Thompson (*accepted*)	£197 10	Veritys Limited	£240 0
Electric Construction Co.	295 0	General Electric Co	225 0
		Crompton and Co	185 0

The Glasgow Tramways committee recommend the acceptance of the following tenders for the conversion to electric lines of various tramway routes:—Whiteinch to Anderston Cross, A. Stark and Sons £25,739; Langside to Overnewton, A. and J. Faill, £32,610; Anderston Cross to Bridgeton Cross and Bridgeton Cross to London-road terminus, Macartney, McElroy and Co., £20,754; Bridgeton Cross to Dalmarnock-road terminus, Pollokshaws and Pollokshields

Digitized by Google

to Eglinton Toll, and Braehead-street, Rutherglen-road, to Crown-street, D. Murray, £22,973.

The South Shields Corporation have accepted the tender of Messrs. S. Z. de Ferranti (Limited) for switchboard extensions, at £1,047. 2s.

The Victorian Postmaster-General recently accepted the tender of the W. T. Henley's Telegraph Works Co. for the supply of 10 miles of aërial telephone cable at £2,210.

APPOINTMENTS VACANT AND FILLED.

The Gas committee of the Keighley Corporation require an electrical engineer to prepare specifications, &c., of an electric lighting scheme. Further particulars are given in an advertisement, and applications (addressed to the chairman of the committee) must be sent to the town clerk (Mr. George Burr) by May 1.

The Hull Electric Lighting committee require two junior assistants. Applications to city electrical engineer (Mr. A. S. Barnard), Electric Light Station, Dagger-lane, Hull, by April 20. See advt.

A fitter is required for the District Asylum, Millingar, with a sufficient knowledge of electrical engineering to enable him to take charge of and keep in repair an installation of 400 incandescents and 13 arc lamps. Applications to the resident electrical superintendent. See advertisement.

Mr. Alec Scott has been appointed electrician-in-charge at the Folkestone Electricity Co.'s works.

Mr. George E. Gittins has been appointed assistant in the Physics department of the Blackburn Municipal Technical School. Salary £110 per annum.

Mr. S. E. Bastow, of Hull, has been appointed clerk of works at Barnsley.

Mr. C. E. Squire has resigned his position as superintendent of the public lighting department at Blackpool, and has entered the service of the British Insulated Wire Co.

BUSINESS NOTICE.

Messrs. Meirowsky and Co., mica merchants, have removed from 10, Glasshouse-street, W., to 52, Queen Victoria-street, E.C., to which address all future communications should be made. Telegrams "Meirowsky London." Telephone 657 Bank.

BANKRUPTCIES, LIQUIDATIONS, &c.

D. U. Paine, electrician, 84, Gloster-road, Brighton, has been adjudicated bankrupt.

A receiving order has been made against J. E. Stott (trading as James E. Stott and Co.), electrician, 10, Wood-street, Byrom-arcade, Huddersfield.

Claims against Electricity (Limited) must be sent to the liquidator, Mr. P. W. Davis, 61½, Fore-street, London, E.C., by May 2.

It has been decided to wind up voluntarily the Electric Lighting Extension Syndicate (Limited), to approve an agreement with the Penny-in-the-Slot Electric Supply Syndicate (Limited), and to appoint Mr. C. O. Bastian liquidator.

It has been decided to wind up the Faraday Electrical Engineering Co. (Limited) voluntarily. Mr. Jas. C. Bowes, 203, West George-street, Glasgow, is liquidator.

Electrical Trades' Directory and Handbook, 1899—*Correction.*—By a clerical error the name of Mr. Mervyn J. P. O'Gorman was included under the heading of "Electric Tramway Contractors," on p. 751 of the 1899 edition of this work. The entry should not have appeared under this heading, as the firm of O'Gorman and Cozens-Hardy practice exclusively as consulting engineers, and are not contractors or manufacturers of any kind of plant, apparatus or materials.

Sale by Tender.—Pursuant to an order of the High Court there is for sale by tender the stock-in-trade, plant, furniture, fixtures, goodwill and British patents owned by the Elieson Lamina Accumulator Co. (Limited). Particulars will be found set out in an advertisement on another page. It will be seen that tenders are to be sent in not later than Wednesday, April 12.

King's College (London).—The special evening course of lectures and laboratory work on alternating currents commences on May 1.

"Snowdrift" Lubricants, &c.—A well-prepared catalogue of "Snowdrift" lubricants and the special types of automatic and other lubricators manufactured by Messrs. Snowdon, Sons & Co., Ltd., of Millwall, London, E., is to hand. The catalogue also contains particulars of vulcanised india-rubber goods, asbestos packings, &c.; beltings, boiler coverings, &c.; and forms a useful trade guide.

New Apparatus Catalogue.—Messrs. John J. Griffin and Sons, Ltd., of 20–26, Sardinia-street, London, W.C., forward a list of new apparatus for use in electrical, chemical, and general research work.

Interior Conduit Wiring.—We have received from the Simplex Steel Conduit Co., Ltd., an admirably arranged and complete catalogue of the material used for their system of house-wiring. In the Simplex system special steel tubes are used, with a longitudinal seam which leaves sufficient springiness for the connection and corner pieces to be slid over the ends, a serviceable connection being thus made without screwing the ends of the tube. The erection of the conduit is thus extremely easy, and justifies the name "Simplex." Connection pieces, bends, junction-boxes, &c., to meet every possible requirement are quoted for in the catalogue, and some new forms of these have recently been introduced. Among them we may mention the "half-normal" bend (Fig. 1), and some practical outlet boxes for pendants and other fittings. Fig. 2 is an "inspection" sharp bend, which should prove very

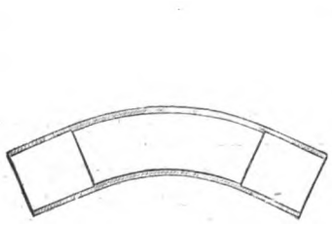

FIG. 1.

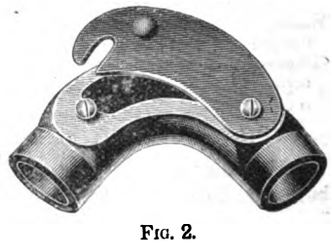

FIG. 2.

practical in situations where sharp bends cannot be avoided. It is claimed that the cost of installations on this system will compare favourably with those in wood or other casing.

Cassier's Magazine.—The contents of the April issue include "Electric Power in Steel Making," "Water Softening," "Modern Pumping Machinery for Mine Service," "America's Export Trade," "Engineering in Africa and the Far East," "Industrial Imperialism," "Horseless Carriages Four Hundred Years ago," and "American Lake Shipping and Casualties."

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) on March 29 and March 30, with the ports of destination:—

Argentina—Buenes Ayres, £225 (including £190 telegraph material); Rosario, £9. *Australasia*—Launceston, £186; Melbourne, £170; Otago, £7; Sydney, £102; Wellington, £234. *Borneo*—Labuan, £42 (telegraph material). *Brazil*—Rio Janeiro, £79. *British Guiana*—Demerara, £24. *Ceylon*—Colombo, £284. *Chili*—Valparasio, £100. *Egypt*—Alexandria, £64. *Holland*—Amsterdam, £90. *Hong-Kong*, £1,020. *India*—Calcutta, £11; Madras, £10. *Italy*—Genoa, £285; *Japan*, Yokohama, £96. *Russia*—Reval, £24; St. Petersburg, £180 (including £125 telegraph material). *Siam*—Bangkok, £29. *South Africa*—Cape Town, £44; Chinde, £13; Delagoa Bay, £5; Durban, £19 (including £28 telegraph material). *Uruguay*—Monte Video, £70. Total (for two days) £5,452, against £7,428 for one week last year (March 30 to April 5).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Blackburn.—The new electric tramways are in great favour. Last week 44,000 more passengers were carried than in the corresponding week of 1898, and the increased receipts amounted to nearly £450.

Blackpool.—The receipts of the electric tramway department for the last financial year were £18,196, against £15,376 in 1898, £13,223 in 1897, and £9,869 in 1896. It is proposed to give a 2½ minutes' service on the promenade.

Buenos Ayres.—The popularity of electric traction is strikingly shown by the results of the competition between the Belgrano Electric and the New Tramways Companies of this city. According to the *Review of the River Plate* both companies run through the same streets from Paseo de Julio to Recoleta, and while the cars of the former are generally crowded, those of the horse system are virtually empty. At night and in the morning the cars of the Electric Co. are always crowded, and the local train service to Palermo is, in consequence, suffering considerably.

Canterbury.—An inquiry was held last week into the application of the Town Council to borrow £13,250 for electric lighting extensions. The consulting engineer (Mr. Robert Hammond) submitted technical details. He said that the amount already sanctioned for electric lighting was £23,000. No greater success had ever been achieved by any local body than by Canterbury, for at the recent formal opening the orders in hand were sufficient to exhaust the capacity of the whole plant. The number of applications was then 172, of which 102 were connected up. The demand was increasing. There was no opposition.

Crewe.—Before sanctioning the Council's application for a loan for electric lighting purposes, the Local Government Board ask the probable revenue of the proposed supply works, and as to the suitability of the site.

Digitized by Google

Darlington.—The borough engineer has been authorised to obtain tenders for electric lighting plant.

Derby.—The gas lamps are to be adapted for incandescent electric lighting in those streets where electric light mains are laid. The work has been authorised on condition that the cost of conversion does not exceed £1 per lamp, and that the charge for electric lighting does not exceed the present cost of gas.

Eastbourne.—The Council have definitely accepted the offer of the Eastbourne Electric Light Co. for the sale of the company's undertaking for £83,000. The transfer will take place at the end of the year.

Edinburgh.—On the question of creating a special reserve fund for the electricity department, the Electric Light committee report that they cannot recommend the Council to depart from the statutory provisions of their provisional order at present, and recommend that no special or separate fund for renewals should be formed apart from the reserve fund already established which should be made up to its maximum.

Glasgow.—Mr. H. F. Parshall has been appointed consulting engineer to the Tramway department in connection with the conversion of their lines to the overhead trolley system of traction, at a remuneration of 2½ per cent. on the capital outlay.

The following estimate prepared by the general manager of the tramways (Mr. John Young) as to the conversion of six additional routes (Section II.) has been approved by the Tramways committee. The estimates include permanent way alterations and renewals, including bonding and ducts for feeders, and also overhead construction :—

Paisley-road and Parkhead route	£35,000
Paisley-road and Possilpark route	11,400
Pollokshields and Garscube Cross route	2,800
Maryhill and Mount Florida route	54,050
Langside and Seamore-street route	4,900
Paisley-road and Oatlands route	2,150
	£110,300
Less cost of renewal of lines in ordinary course	55,000
	£55,300

The provision of depots at Kinning Park, Whitevale, and Maryhill will entail an expenditure of £13,814.

Great Grimsby.—A Local Government Board inquiry was held yesterday (Thursday) into the application of the Council to borrow money for electricity supply. The scheme provides for supply for lighting and power purposes.

Hanley.—Sanction to borrow £5,000 for electric lighting extensions has been applied for.

Hereford.—The Electric Lighting committee hope to be in a position to supply electric current by October. The committee reported the acceptance of tenders for the erection of the station buildings last week.

Hull.—Extensions of the mains, estimated to cost £1,323, were authorised by the Electric Lighting committee last week. The chairman (Councillor Skinner) made a statement on the financial position of the department, and said that owing to the great and unexpected demand for current from districts that had not been contemplated, a sum of £5,339. 3s. 6d. in excess of the loan sanctioned for new works had been expended in extending the mains in streets not included in the original scheme. To meet this over-expenditure, and in anticipation of requests to extend the mains to other districts, the question of borrowing another £10,000 is being considered. The new works at Sculcoates-lane were opened during the year. The whole of the works were designed by and carried out under the sole superintendence of their electrical engineer (Mr. A. S. Barnard), and in recognition of the time, energy, and ability Mr. Barnard has devoted to the work, and of the expense he had saved the committee, it has been decided to grant Mr. Barnard an honorarium of 100 guineas.

Kingston-on-Thames.—£15,000 is to be borrowed for electric lighting extensions.

Kingstown (Dublin).—The Council are considering a proposal of the Municipal Industries Syndicate to take a transfer of their provisional order and to establish electricity works.

Leigh.—Sanction to borrow £10,000 for electric lighting purposes has been received by the council.

Llanrwst (N. Wales).—The electricity works of the Llanrwst Electricity Supply Co. were formally opened by Earl Carrington on Thursday evening last week.

Motherwell.—The plans of the proposed electricity works have been approved by the Police Commissioners, and the consulting engineer (Prof. A. B. W. Kennedy) has been instructed to proceed with the scheme.

Musselburgh.—An agreement has been entered into by the Town Council with the Drake and Gorham Electric Power and Traction Co. for the establishment of electricity supply works. The company undertake to supply current for private lighting at 6d. per unit, and for public lighting at 4d. The Council reserve the right of purchase.

Newington (London).—The following charges for current has been decided upon :—6d. per unit for first hour, 4d. second hour, 3d. after. For power a uniform rate of 2½ per unit will be charged.

Oldham.—The Electric Light committee are recommended by their consulting engineer (Prof. A. B. W. Kennedy) to complete the work of doubling the pressure of supply and to carry out certain other alterations and extensions, at an estimated cost of £20,000.

Port Adelaide (South Australia).—The electricity supply works of the South Australian Electric Light and Motive Power Co. were formally opened on Feb. 1. The works have been erected to the plans and specification of Mr. W. W. Crawford, the company's consulting engineer and the Australian representative of Messrs. Johnson and Phillips. The generating plant consists of five 440-volt continuous-current Johnson and Phillips dynamos and five compound condensing high-speed engines. The feed pumps are of the Worthington type. The cables and arc lamps have also been supplied by Messrs. Johnson and Phillips, and the accumulators by the D.P. Battery Co.

St. Pancras.—Forty-nine additional arc lamps are to be erected, at an estimated cost of £3,583. Tenders are to be invited for two 750 H.P. steam dynamos, and two boilers, for the Regent's Park station. The cost of these additions is estimated at £19,000.

St. Saviour's, Southwark (London).—The Board of Works have resolved that if the City of London Electric Lighting Co. do not, within one month, commence to erect workmen's dwellings for the people dehoused several years ago, when the company's works were being built at Bankside, legal proceedings will be commenced to compel the company to carry out their agreement.

Shoreditch (London).—The Vestry have declined to adopt the recommendation of the Lighting committee to enter into a special contract for the supply of current for power purposes to Messrs. Wertheimer, Lea and Co. for 21 years. It was considered impolitic to make an agreement for so long a period, and the terms proposed were deemed too favourable to the company. The proposal was to supply current for lighting at 3d. per unit for an annual consumption of 50,000 units, and for power purposes at 1½d. per unit for 100,000 units per annum, 1¼d. per unit for 75,000, and 2d. per unit for under 75,000 units yearly.

Sierra Leone.—Telegraphic communication between Freetown and Waterloo was available for the first time on April 4.

South Shields.—The Electric Lighting committee have reduced the charge for electric current from 3d. to 2d. per unit after the first hour's maximum demand at 7d. The Corporation's electricity undertaking has made rapid progress, and, in view of the recent increase in the price of gas, the reduction in the charge for energy announced will lead to increased popularity for the electricity department.

The committee have approved the scheme for further extension of the electricity supply undertaking, at a total estimated cost of £21,150, sanction for the borrowing of which sum is to be applied for.

Stock Exchange Call Board.—The *Financial News* states that an electric call board has been erected in the London Stock Exchange, upon which are placed a number of figures in black on a white ground-glass background. These groups of figures indicate members' numbers, and on a member being inquired for, or called up, a loud electric alarm is sounded, and the number is illuminated by an incandescent electric lamp. According to the same authority the new board is the source of considerable speculation—of the betting order.

Sunderland.—The Corporation have come to an arrangement with the local tramways company to take over the tramways from Jan. 1 next. The purchase price is £34,000. The Corporation are at present seeking powers to introduce electric traction.

The Government and the Telephone.—The Parliamentary committee of the Liverpool Corporation have decided to co-operate with Chambers of Commerce and other public bodies in opposing the Government Telephone Bill on the ground that undue advantages are offered to London subscribers compared with those available in provincial centres, metropolitan subscribers benefiting exclusively from the Imperial funds, and in the abolition of the 10 per cent. royalty. The committee hold that the powers granted under the Bill to municipal authorities to establish telephone systems will result in complications, and that a central authority to work the whole telephone system of the country should be established.

A deputation, representing Glasgow, Aberdeen and Paisley, met Mr. Hanbury, M.P. (who will have charge of the Government's measure), at Preston on Wednesday, to discuss with him the question of telephonic municipalisation. Application was made by

Digitized by Google

representatives of the Press for admission to the meeting, but Mr. Hanbury did not see his way to accede to the request. He stated that he thought it would be wholly inadvisable to have the proceedings reported in the newspapers, his interview with the deputation being entirely confidential. His chief object in meeting the deputation was to discuss the details of the Treasury minute (which has yet to be submitted to the House of Commons) relative to the proposed measure. To give the National Telephone Co. the benefit of the publicity of these details at this stage, he remarked, would be to "upset the coach" altogether. Edinburgh, having resolved not to apply for a municipal telephone licence, sent no delegate. It is understood that Mr. Hanbury indicated to the deputation that the proposed restriction of only granting licences to municipalities with populations of over 50,000 would be struck out, and that there is every reasonable prospect of an amicable settlement between the State Department which Mr. Hanbury represents and the municipalities interested regarding the question of wayleaves and the safeguarding of the rights and interests of municipalities at the end of 1911.

Trade of France.—In his report on the trade and commerce of France for the year 1898 Mr. H. Austin Lee, commercial attaché at the Paris Embassy, refers to the continued activity in the demand for electrical plant and apparatus. Exported dynamo electric machinery shows an increase of £8,000 over 1897 (from £48,000 to £56,000), and imports an increase from £132,000 in 1896 to £148,000 in 1898. The exportation of automobile vehicles amounted in 1898 to £68,000, a marked increase over the preceding year.

Tramway Extensions in London.—The London County Council propose to construct the following tramways in the northern, north-western and west central districts of London :—

1. From Theobalds-road, through Russell-square, Woburn-place, Tavistock-square, and Seymour-street, to Crowndale-road.
2. Crowndale-road from High-street, Camden Town to Pancras-road.
3. Along Euston-road from King's Cross to Marylebone.
4. Along Albany-street and Park-street.
5. Along Gower-street and George-street to High-street.
6. Along York-road from King's Cross to Camden-road and through Leighton-road.
7. Continuation from Hampstead-road in Tottenham Court-road to Grafton-street.
8. Continuation in Prince of Wales-road to Haverstock Hill.

Vienna.—Under a recent charter the Municipal Council is authorised to transfer its rights and privileges for tramway construction on specific conditions, and an agreement has been entered into with Siemens and Halske Aktien Gesellschaft, of Berlin, who are to form an Austrian company to take over the concession till 1925, when the entire system of electric tramways will pass into the hands of the town without payment, the Council reserving the right of taking it over at a valuation, either in 1914 or 1920. The existing tramways are to be transformed into electric lines, and the company will also undertake to construct, within four years, an extensive network of lines, which, together with the present tramways, will extend over about 300 kilometres, or nearly 200 miles. Overhead wires are to be allowed, except in the Ringstrasse. The network of electric tramways to be constructed will connect the outlying districts with each other and with the railway termini, and, when completed, will greatly increase the facilities for locomotion in Vienna.

Whitechapel (London).—A loan of £78,500 is to be borrowed from the London County Council for joint electric lighting and refuse destructor works. Mr. Arthur Wright intimated to the Board of Works last week that the work of laying electric light mains would be commenced forthwith. The question of the appointment of Mr. W. C. P. Tapper (Mr. Wright's assistant) as resident electrical engineer has been left in the hands of the Electric Lighting committee.

Wigan.—Now that the Council are definitely committed to an electric lighting project, attention is directed to the advisability of acquiring the local tramways and introducing electric traction. At the meeting of the Council, on Wednesday, the Tramways committee were authorised to open negotiations with the Tramways Company.

Willesden (London).—The Council's electrical engineer (Mr. E. T. Ruthven Murray) has been instructed to report upon the advisability of constructing electric tramways in the district.

Workhouse Lighting.—The Eccleshall Guardians will shortly hold a special meeting to consider Mr. H. W. Ravenshaw's electric lighting scheme.

The Barton (Lancs.) Guardians propose to borrow £3,355 for the electric lighting of their new workhouse and infirmary.

The Pontefract (Yorks.) Guardians have adopted the recommendation to light the workhouse buildings electrically.

Zomba (Central Africa).—An electric lighting scheme has been decided upon for this town, which is the headquarters of the British South Africa Co. in Northern Rhodesia. Only 150 16 c.p. lamps will be required for street lighting at the outset.

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. CHAPMAN and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application an asterisk is affixed.*

February 16, 1899.

11,158A. H. H. LEIGH. London. Improvements in electrical couplings for railway cars (F. J. Sprague, United States). [Date claimed under Patents Rule 19, May 16, 1898.]*

11,158B. H. H. LEIGH. London. Improvements in pilots apparatus and reversing mechanism for controlling electric motors (F. J. Sprague, United States). [Date claimed under Patents Rule 19, May 16, 1898.]*

February 13, 1899.

3,137. J. J. GREEN. Halifax. Improvements in the construction of electric conduits or cable carriers.

3,141. A. BROADBENT. Liverpool. Temporary cord connections for telephone switchboards, &c.

3,151. C. A. LEE. London. New or improved apparatus for imparting a preliminary heating to refractory filaments of electric lamps.

3,152. W. H. WILLATT. Hull. A means of operating hydraulic machinery by electricity.

3,160. H. SMITHSON and E. R. SHARPE. Manchester. Improvements in and relating to electro-magnetic cut-outs and other like apparatus, specially applicable to electric arc lamps.

3,182. G. H. CONDICT. London. Charging stand and contact for storage batteries. (Date applied for under Patents, &c., Act, 1883, Sec. 103, July 18, 1898, being date of application in United States.)*

3,187. A. M. TAYLOR and C. H. GREENBANK. London. Improvements in and connected with road vehicles driven by electric current from conductor.

3,189. F. H. WITHYCOMBE. London. Improvements in insulators.*

February 14, 1899.

3,233. L. BELKNAP and A. SUNDH. London. Improvements in cables for carrying electric currents.*

3,252. C. WIGHTMAN and A. HUDSON. Bradford. Improvements in lining electric wood casings or conduits with steel or other metallic substances.

3,269. M. RAILING. London. A new or improved tilting device for the shades of electric incandescence lamps.

3,316. R. B. PAINTON and W. H. BAINBRIDGE. London. Improvements in or connected with electrically-propelled and/or controlled vehicles.*

February 15, 1899.

3,339. E. G. PINK. London. Improvements in electric traction.

3,374. C. H. MOUNSEY and J. F. WALSH. London. Improved method of and means for correctly and automatically guiding the trolleys of the connecting arms of cables of electric trams, electric railways and the like.

3,387. J. E. WINSLOW. London. Improvements in trolley apparatus for use in connection with electric traction.*

3,389. H. MOUL. London. Jointing conductors of the metal oxides to wires in incandescent electric lamps.

3,391. J. ARCHBUTT. London. An improved connector for electric light and power circuits for theatrical and other purposes.

3,392. POWELL-JONES AND CO. London. Improvements in automatic switches for starting and stopping electric motors.

February 16, 1899.

3,417. W. H. WILLATT and A. E. SEATON. Hull. A means of operating hydraulic or pneumatic machines and tools, and forcing water into boilers and other vessels by electricity.

3,440. E. DICK. Manchester. Improvements in and connected with means for electrically lighting railway carriages.*

3,469. L. ENCAUSSE and L. ENCAUSSE. London. Improved primary battery.

3,477. R. DUCORNOT. London. Safety contact interrupter for suspended electric wires or cables.

February 17, 1899.

3,528. R. P. GERLAND. London. Improvements in automatic electrically signalling the adjustment of dummy clocks.

3,531. E. A. JAHNCKE. Improvements in or connected with electric batteries.

3,570. W. O. ROOPER. London. Improvements in or connected with storage batteries.

3,586. F. FABER. London. An arrangement for collecting accumulator cells and the like.*

3,591. L. M. ERICSSON. London. Improvements in telephone switch apparatus.*

3,594. H. BAGGETT. London. Improvements in arc lamps.

3,597. A. J. BOULT. London. Improvements in or relating to electric railway switching and signalling apparatus. (The Continental Hall Signal Co., Belgium.)*

February 18, 1899.

3,648. A. J. O. Chalandre, L. J. B. Colas and C. J. Gerard. London. Improvements in or relating to the electrolysis of salts in solution and apparatus therefor.
3,665. O. Imray. London. Impro vements in electric incandescence lamps. (W. Hernst, Germany.)

February 20, 1899.

3,704. R. Riley, T. Winstanley and S. Riley. Manchester. Improvements in and appertaining to electric street tramways.
3,717. O. Ward, Jun. Glasgow. Improvements in switch throwers.*
3,734. W. Borchers. London. Improved process for electric smelting or reducing.*
3,735. W. Börchers. London. An improved method of and apparatus for utilising the waste gases and heat from electric furnaces.*
3,736. J. Skwirsky. London. Improvements in secondary batteries.*
3,742. A. C. Brown. London. A combined thermo-electric or electro-thermal lamp.
3,746. W. J. Murphy. London. An improved electric switch.
3,754. P. F. W. Simon, H. H. Berry and C. Rayner. London. An improvement in electrical wall plugs.*
3,762. R. J. Crowley and A. C. Oakes. London. Improvements in wireless telegraphy through water.
3,773. W. J. Murphy. London. An improved dynamometer for use in laying submarine cables.
3,774. L. H. Newton, R. R. F. Neville, S. P. Newton and E. Tew. London. Improvements in galvanometers and the like.*
3,784. F. H. Badger and W. J. Plews. London. Improvements in electric safety appliances.

February 21, 1899.

3,836. R. J. Wallis-Jones and H. W. Couzens. London. A new or improved process for roasting or calcining mineral substances by electrical currents, especially adapted to the manufacture of Portland and like cements.
3,842. G. D. Granger. London. Improved electrically energised pendulum for use in clocks and for other like purposes.
3,861. T. Carles. London. Improvements in telegraph and telephone cables.
3,869. R. D. Cranston and S. M. Williams. London. Coin controlled and registering telephone apparatus.*

February 22, 1899.

3,893. Anchor Electric Co. and E. Freund. London. Improvements in electrical signalling apparatus.
3,899. J. F. Pierce. Oxford. "The Oxford watch lamp," an improvement in electric cycle lamps.
3,904. A. E. Slater. Derby. Improvements in telephone exchange switches for use in public central stations, large institutions, police service and the like.
3,910. R. Kennedy. Leeds. Improvements in starting alternating single-phase electromotors and in apparatus therefor.
3,936. A. Bodenheimer. London. Electric bell for velocipedes.
3,943. J. H. Betteley. London. Improved means for establishing connection between underground electric circuits and electromotors of vehicles.
3,947. T. Carles. London. Improvements in apparatus for applying electric currents of high frequency to telegraphy.

February 23, 1899.

4,001. E. N. Bray. Glasgow. Improvements in and relating to starting switches and resistances for electric motors.
3,999. J. Milnes. Manchester. Improvements in electric traction for tramcars and the like.
4,007. R. E. B. Crompton and E. A. N. Pochin. London. Improvements in electrically controlled switches.
4,027. J. H. Hollyer. Droitwich. Improvements in automatic electric warning signals for railways and the like.
4,046. V. A. Fynn. London. Improvements in or connected with electric motors and generators and other electric apparatus and instruments.
4,059. T. D. Farrall. London. Improvements in incandescent electric lamps.
4,065. Veritys (Limited) and L. J. Steele. Birmingham. Improvements in electrical switches.
4,068. S. S. Bromhead. London, A new and useful method of manufacturing electric resistances. (W. C. Heraeus, Germany.)*
4,078. D. Honeywood. London. A new or improved machine tool particularly applicable for refacing or turning commutators of electric generators and the like.
4,082. T. H. Stone. Oxford. Improvements in accumulators and storage cells portable and stationary.
4,088. W. Lynes. Birmingham. An improved lamp holder for incandescent electric lamps.
4,119. W. Rutherford. Birmingham. Improvements in the mode and means for operating the poles or masts of electrical cars or vehicles for tramways.*
4,121. W. Best. London. Improvements in miners' safety lamps and in means for electrically igniting the same.
4,122. W. Best. London. Improvements in or connected with induction coils especially applicable for use in mines.
4,123. S. G. Brown. Bournemouth. Improvements in electric glow and arc lamps.
4,124. H. J. Dowsing. London. An improvement in electric stoves.
4,137. P. L. Schmidt. London. A new or improved galvanic bandage.*
4,158. A. Wydts and G. Weissmann. London. Improvements in transformers for continuous electric currents. (Date applied for under Patents, &c., Act, 1883, Sec. 102, August 4, 1898, being date of application in France.)

February 25, 1899.

4,190. R. F. Hall. Birmingham. Improvemenrs in electrically propelled vehicles.
4,210. W. Kingsland. London. Improvements in and connected with electrical traction.
4,224. W. H. Wheatley. London. An electrical recording instrument. (H. R. Lockhart and R. O. King.)
4,231. W. C. Johnson and A. Wunderlich. London. Improvements in arc lamps.*
4,232. Société Geoffroy et Delore. London. Improvements in electromotor road vehicles. (Date applied for under Patents, &c., Act, 1883, Sec. 103, August 29, 1898, being date of application in France.)
4,244. H. T. Harrison. London. Improvements in or in connection with primary electric batteries.

Feb. 27, 1899.

4,276. N. Brown. London. Improvements in automatic potential regulators for dynamos. (The Tirrill Automatic Potential Regulator Co. United States.)*
4,283. G. Williams. Catford. An improved electrical sock.
4,312. O. Imbey. London. Improvements in electric welding and apparatus therefor. (G.L. Thompson Manufacturing Co., United States.)
4,313. M. Déri. London. Improvements in alternating current motors.*
4,318. L. Calisch. London. Improved electric signalling device for railways.
4,327. G. Westinghouse. London. Improvements in electro-pneumatic controlling system. (Date applied for under Patents, &c., Act, 1883. Sec. 103, August 20, 1898, being date of application in United States.)

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1898.

2,040. Blenheim. Electrical fire call.
2,389. Sherbin. Secondary batteries.
2,428. Wydts and Rochefort. Electrical transformer for currents of high potential and variable frequency.
2,455. Burn and Brown. Electric contacts suitable for railway signalling and other purposes.
2,584. Wise (Pieper). Manufacture of electric glow lamps.
3,431. Beach. Anodes for electrolytic operations.
3,496. Andrews. Electrical cut-out apparatus.
3,850. Geipel, Lange and Sattrick. Holders for electric glow lamps.
4,588. Bathurst. Method of and means for holding the bases of electrical fittings within boxes, or upon other surfaces.
5,064. Belfield (Lamme). Non-synchronous electric motors.
5,066. Belfield (Davis and Harder). Electric switches.
5,177. Sayers and Mavor and Coulsons (Limited). Dynamo electric machines.
5,208. Actiengesellschaft fur Fabrikation von Broncewaaren und Zinkguss vorm. J. C. Spinn and Sohn and von Romocki. Electrically operated gas valves for burners.
6,024. Sykes. Conduits for electric cables.
6,135. Nernst. Electric incandescence lamps.
6,773. Stewart. Street lanterns for the reception of incandescent electric lamps.
6,902. Aldred and Carr. Detail of electric tramways and railways on a road-suface sectional-contact system.
6,990. Weston. Electrical measuring instruments.
7,058. Underhill and Northey. Method of preventing the corrosion of electric battery connections.
7,751. Société Guyenet et de Mocomble. Lifts worked by electricity with hydraulic braking apparatus. (Date applied for under International Convention, Nov. 12, 1897.)
8,262. Rayner (Leitner). Controlling device for electric motor vehicles and the like.
15,496. Browne and Martineau. Electrical time switches.
18,754. Love. Electric tramways and railways on the conduit system.
23,529. British Thomson-Houston Co. (Limited) (Green). Method and system for generating and distributing electric energy.
23,530. British Thomson-Houston Co. (Limited) (Green). Method and apparatus for generating and distributing electric energy.
23,531. British Thomson-Houston Co. (Limited) (Green). Method and apparatus for generating and distributing electric energy.
24,172. Schloss. Process for obtaining a permanent electrical contact at the covers of voltaic cells.
24,747. Houpied and Girard. Electric sparking devices, more particularly for igniting devices of motors operated by explosive mixtures. (Date applied for under International Convention, June 13, 1898.)
24,993. Giorgi. Telegraphic receivers.
25,259. K. Obst. Electrical speed indicators.
25,479. Canfield. Electric igniter or sparker for gas, oil or vapour engines.
25,567. Siemens Bros. and Co. (Limited) (Siemens and Halske Aktien-Gesellschaft). Apparatus for transmitting motion to a distance by means of electrical energy.
26,026. Heys. (Silberberg.) Galvanic batteries.
26,067. Gover and Proctor. Holder for electric glow lamps.
26,068. Siemens Bros. and Co. (Limited) (Siemens and Halske Aktien-Gesellschaft). Electric glow lamp fittings.

COMPANIES' MEETINGS AND REPORTS.

ANGLO-PORTUGUESE TELEPHONE CO. (LIMITED).—At the twelfth general meeting of this company, held on March 29, the directors report for the year to Dec. 31 last was adopted. The amount to credit of profit and loss, after making all deductions, and including balance brought forward, was £6,192. 12s. 2d., and after placing £3,000 to suspense account, and carrying forward £1,942. 12s. 2d., a dividend of 2½ per cent. was approved. Expenditure on capital account for the year amounted to £1,801. 6s. 3d. The number of paying subscribers at Dec. 31 was:—Lisbon, 1,326; Oporto, 983; showing a decrease in subscribers of 139, but an increase in value of £81 during the year. The continuance of the high rate of exchange between the two countries again entailed very serious loss on the company, amounting on the year to £3,824. 13s. 1d., an increase of £461 over the previous year. This loss is rapidly approaching 25 per cent. of the gross receipts, and has consequently increased the percentage of working expenses enormously.

AUTOMATIC TELEPHONE CO. (LIMITED).—The adjourned meeting of this company was held yesterday (Thursday), Mr. M. E. Alexander presiding. The chairman, who was the only director present, said he trusted the decision which they would arrive at that day would be beneficial to their interests. Mr. Barlow stated that Mr. Margowski had refused permission to the committee to inspect the books of the company. It was maintained by Mr. Margowski and the secretary that this was not a legal meeting, but he was of a different opinion. The point for them to settle was whether that gentleman should be allowed to continue to dictate to the shareholders the future policy of the company. It was an important matter to them what attitude towards the company was adopted by Mr. Seligman-Lui. He understood that, since the last meeting, that gentleman had been approached on behalf of Mr. Margowski, but, apparently, he had not materially changed his opinion. The object of the resolutions to be submitted to the meeting was to give the shareholders a voice in the control of a business, which he believed to be capable of great and valuable development. Mr. White, solicitor to Mr. Seligman-Lui, said that his client had been interviewed in Paris by Mr. Moore and Mr. Penny, with the object of finding out on what terms he would resume his duties as consulting engineer; and he understood that Mr. Moore promised Mr. Seligman-Lui's requirements should be conceded. Mr. Moore denied having made any such promise. He might add that Mr. Seligman-Lui laid great stress on his being allowed freedom to work for any other company, which, under existing contracts, he could not do. He (the speaker) replied that he did not think the company would give him complete freedom in regard to companies having anything to do with telephones, although they might do so in regard to electric light and other companies. Mr. White, in the course of further remarks, said that, if Mr. Margowski were removed, he thought Mr. Seligman-Lui would not raise any further difficulties. On the motion of Mr. Parker, seconded by Mr. Ettinghausen, a resolution was passed to remove forthwith Mr. Margowski from the office of managing director. The articles of association, so far as they referred to the voting power of the shareholders, were then altered in such manner as to prevent Mr. Margowski from out-voting the other shareholders. It was further decided to authorise the committee to take such steps as they might be advised to be necessary to enforce these resolutions.

CITY OF BIRMINGHAM TRAMWAYS CO. (LIMITED).—At the meeting of this company, held last week, the Chairman (Mr. James Ross) said no further progress had been made in their negotiations with the Corporation. A report of the Public Works Committee in favour of municipalisation was recently approved by the Council. The company was formed in 1896, upon a resolution passed by the Council agreeing to give them 21 years' leases of their tramways, and he still relied upon the good faith of the Coporation to see that the company received fair treatment. They were ready and willing to deal with the Corporation on the basis of any arrangement that would leave the company in as good a financial position as it was now in. He had hoped long before now to have taken part in a work of great public benefit, by substituting a convenient and rapid electric service for their cumbersome and antiquated steam trams. An improved method of traction was necessary to meet public requirements. He was still hoping that when Birmingham saw the improvements in traction that were being introduced in other places in Great Britain, and the benefit that these improvements conferred, the citizens would desire something better in the way of tramway accommodation than they possessed.

EVERED AND CO. (LIMITED).—At the annual meeting held last week the chairman (Mr. R. B. Evered) moved the adoption of the report and accounts, which, he said, showed, after providing for debenture interest amounting to £2,416. 13s. 4d., a net profit of £25,698. 16s. 6d., making, with £6,361. 11s. 8d. from 1897, £32,060. 8s. 2d. to be dealt with. An interim dividend at the rate of 7½ per cent. per annum to June 30, had been paid, and it was now proposed to pay a dividend at the rate of 7½ per cent. per annum for the remaining six months, and pay a bonus of 2½ per cent. per annum. The remainder of the profits would be used in writing off plant (£2,000), clearing off the goodwill (£4,000), writing off buildings (£1,000), placing to an equalisation of dividends account (£1,000), and £6,986 would be carried forward. The business continued to make good progress, and the number of customers was increasing. Despite higher prices and ever-increasing competition, their works were fully employed in all departments. The stocks of copper and other raw material figuring on the balance sheet at £100,707. 1s. 9d. had been taken at prices ruling in 1897. The report was adopted, and the retiring directors re-elected.

FOLKESTONE ELECTRICITY CO. (LIMITED).—The third general meeting of this company was held at the works last week. The directors' report stated that the prospects of the company were very satisfactory. The contract with Edmundson's Corporation stipulated that the works had to be completed by July 1, 1898, so that practically the company had only the benefit of six months' working up to Dec. 31. At the end of the financial year the equivalent of 10,089 8-c.p. lamps was being supplied, and up to the end of February this number (including street lighting) amounted to 11,861 lamps. There was a profit on revenue account of £405. 2s. 3d., which was carried forward.

GUILDFORD ELECTRICITY SUPPLY CO. (LIMITED).—At the annual meeting last week the chairman (Dr. F. R. Russell) said they had made a profit during the past year of £300, for what was practically the second year's working. They had applied to the Board of Trade for a new order extending the company's area of supply to the parishes around Guildford. That extension would entail increased expenditnre in laying down more cables. Mr. Money-Kent congratulated the shareholders on the accounts presented. He said that last year he showed that for the end of a first year, with an output of only 15,000 units, they were doing very well. He also prophesied that at the end of another twelve months they would be doing well, and he thought the figures before them showed that. Last year their cost per unit came out at 11d.; this year at about 5½d. (5.24). Their work compared favourably with other two-year-old companies.

THAMES IRONWORKS AND SHIPBUILDING CO. (LIMITED).—A very favourable report was presented to the meeting of shareholders last week in connection with the past year's work of this company. Arrangements have been made for taking over the well-known works of Messrs. John Penn and Son, at Greenwich. The report states that the system adopted some years back of giving every workman in the company's employ a direct interest in the work he has in hand has proved in every way satisfactory.

WESTERN UNION TELEGRAPH CO.—This Company have issued their report for the quarter ended March 31, 1899. The following statement, dated March 8th, shows the condition of the Company at the close of the quarter ended Dec. 31, 1898:—

Surplus Oct. 1, 1898, as per last quarterly report.....		$8,049,213 99
Net revenues, quarter ended Dec. 31, 1898		1,459,194 22
		$9,508,408 21
From which deducting for—		
Dividend of 1¼ per cent. paid Jan. 16th	$1,216,987 50	
Interest on bonded debt	224,273 00	
		$1,441,260 50
Left a surplus Jan. 1, 1899, of		$8,067,147 71
The net revenues of the quarter ending March 31st, based upon nearly completed returns for January, partial returns for February, and estimating the business for March will be about		1,250,000 00
		$9,317,147 71
From which appropriating for—		
Interest on bonds		224,237 00
		$9,092,874 71
It requires for a dividend of 1¼ per cent. on capital stock issued, about		1,216,987 50
Deducting which leaves a surplus, after paying dividend, of		$7,875,887 21

In view of the preceding statements, the Committee recommend that a dividend of 1¼ per cent. on the capital stock of the Company be declared payable on and after the 15th inst.

NEW COMPANIES, STATUTORY RETURNS, &c.

BLACKBURN, STARLING AND CO. (LIMITED).—This company was registered on March 28, with a capital of £12,000, in £1 shares, to acquire and carry on the business of a steeplejack, electrical, heating, ventilating and mechanical engineer, &c., now carried on by Joseph Blackburn. The first subscribers are: Joseph J. Blackburn, electrical engineer; Francis H. Starling, electrical engineer; C. Osborne, electrical engineer; A. T. Ashwell, G. Tutin, E. M. Tinsley and E. H. Bridges. The first directors are: Joseph Blackburn, Frank H. Starling, C. Osborne, and A. Campbell.

INTERCHANGEABLE FLASH SIGN SYNDICATE (LIMITED).—This company was registered on March 22 with a capital of £5,000, in £1 shares, to acquire provisional patent No. 20,027 (1898), granted to Mr. A. D. Douglass, for an interchangeable electric flash sign to carry on the business of electric flash sign manufacturers, advertising contractors, electrical and mechanical engineers, machinists, &c. The first subscribers are: W. T. Todd, W. T. Fowler, H. J. Murray, H. A. Taylor, A. T Palace, R. C. Oldham and G. F. Longden.

HODGES AND TODD (LIMITED).—The statutory return to Dec. 15 gives the capital as £25,000, in £1 shares, of which 757 shares have been taken up and paid for in full.

JULIUS SAX AND CO. (LIMITED).—The annual return to Jan. 24 has been filed. The capital is £20,000, in £10 shares, all of which have been taken up; 1,993 shares have been issued as fully paid and no calls have been made on the others.

Digitized by Google

LONDON ELECTRIC WIRE CO. (LIMITED).—The annual return to Feb. 7 has been filed. The capital is £100,000, in £5 shares (10,000 Preference); 6,280 Preference and 6,893 Ordinary shares have been taken up, and 3,860 of each class are considered as fully paid. The full amount has been called on the remaining 2,420 Preference and 3,033 Ordinary shares.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (since Feb. 2, 1899). Price of silver 27 7/8d. per oz. (April 6). Consols (2¾ per cent.) 110⅛—110⅜ for money, 110 1/16—110 3/16 for account; 2½ per cent. 103¼—103¾ (April 6), Stock Exchange Settling Days: Stocks and Shares Continuation Days, April 11 and 25; Ticket Days, April 12 and 26; Pay Days, April 13 and 27; Mining Share Carry over Days, April 10 and 24.

BRITISH COLUMBIA ELECTRIC RAILWAY CO. (LIMITED).—The half-yearly interest on this company's Four and a-Half per Cent. Debentures, due on 15th inst., will be paid at Messrs. Sperling and Co.'s, 8, Austin-friars, E.C.

ELECTRICAL ENTERPRISE IN RUSSIA.—A syndicate has been formed in St. Petersburg, with a capital of 20,000,000 roubles, for the purpose of establishing and exploiting electric lighting and power undertakings in Russia. The backers of the syndicate comprise the Siemens and Halske Aktien Gesellschaft, the Allgemeine Elektricitäts Gesellschaft and the Union Elektricitäts Gesellschaft, of Berlin, and several German banking houses. Messrs. Rothschild, the Société d'Etudes Russes, of Paris, and the Franco-Russian Electricity Co., of Geneva, are also interested in the syndicate, the head offices of which will be at St. Petersburg.

LEATHERHEAD ELECTRIC LIGHTING AND POWER CO. (LIMITED).—It has been officially announced that this company has never been in operation.

LIVERPOOL.—The Corporation have determined to create 2¾ per cent. redeemable stock to the extent of £1,000,000. The money is required to pay off £750,000 borrowed in anticipation of the present issue, and to meet capital expenditure on electric lighting and traction undertakings, &c.

MUNICIPAL ISSUE.—The Birkenhead Corporation are inviting applications until Monday for an issue of £250,000 2¾ per cent. redeemable stock, at a minimum price of £97 per cent. The loan is for electric lighting, tramway, &c., undertakings.

STEWART ELECTRICAL SYNDICATE (LIMITED).—Mr. Douglas C. Bate, A.M.Inst.C.E., the well-known manager of this company, has been appointed managing director.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed Wednesday, 12th inst., as a special settling day for the further issue of £40,000 Four and a-Half per Cent. Debenture stock of the *Chelsea Electricity Supply Co. (Limited)*, and 24,000 Ordinary fully-paid £5 shares (Nos. 10,001 to 34,000) of the *New General Traction Co.* The committee has ordered the shares of the latter company, as well as the further issue of £100,000 Five per Cent. Perpetual Debenture Stock of the *British Electric Traction Co. (Limited)*, and 20,000 £5 shares, £3 paid (Nos. 1 to 20,000) of the *Calcutta Electric Supply Corporation (Limited)*, to be quoted in the official list. The committee has been asked to appoint a special settling day for £233,334 First Mortgage Four per Cent. Irredeemable Debenture Stock of *Doulton and Co. (Limited)*.

SUBMARINE CABLES TRUST.—Notice is given that on and after April 15 the due coupon will be paid in full by Messrs. Glyn, Mills and Co., 67, Lombard-street, E.C. Coupons should be left four clear days.

TELEGRAPH MANUFACTURING CO. (LIMITED).—Mr. J. S. Harmood Banner has joined the board of this company.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated amount of the traffic receipts of this company for the half-month ended March 31 is £2,333, against £2,309 in the corresponding period of 1898.

NOTES.

THE Corporation of London has placed itself in a remarkable position with regard to the electric lighting of the City, and when Sir COURTENAY BOYLE issues his report on the inquiry he has held into the applications for Provisional Orders of the three companies anxious to compete with the City of London Electric Lighting Co., the City Fathers will still have to extricate themselves from their difficulty by some action of their own. By the agreement between the City authorities and the predecessors of the City of London Co., the former undertook to withhold their consent to the granting of a Provisional Order for the City to any other company before the year 1911, and the same agreement fixed a tariff for the public lighting distinctly advantageous to the Corporation. There was also a clause debarring the Corporation from themselves establishing a competing electricity supply service before the above date. In consequence, the Corporation felt itself bound to withhold its consent when the Charing Cross and Strand, Metropolitan, and Smithfield Markets Companies sought to obtain Provisional Orders. According to the electric lighting law, the Board of Trade, if it finds sufficient reason, has power to dispense with the consent of a local authority, and the Board of Trade inquiry which has just closed has been made with a view to determine whether there is, in this case, sufficient ground to do so. In the meantime, at the instance of Mr. A. C. MORTON, the contract between the Corporation and the Company has been examined by learned counsel and has been declared to be illegal, owing to the fact that Sir JOSEPH SAVORY and some other Commissioners of Sewers and Common Councillors were, at the time, also shareholders in the contracting company.

IT is obviously the duty of the Corporation to approach the City of London Company with a view to getting the contract put upon a legal basis. To consider the contracts dead, and "to let the initiative of legislation come from the other side," as Mr. MORTON suggests, might be good policy if it were merely a question of freeing itself from a troublesome agreement. But if the agreement is declared null and void and no subsequent one is made, might not the electric lighting company be able to recover additional payment for the public lighting supplied during all these years? The situation is, moreover, complicated by one section of the Council being in favour of the Corporation erecting its own electric lighting works, if the contract with the company is no longer valid. As the result of a long discussion, it will be seen that the Court of Common Council was unable to make up its mind, and, to be on the safe side, resolved that, after the evidence of Mr. Ross had been taken, it should not tender any further evidence at the Board of Trade inquiry. The Streets Committee has been directed to take further opinion of counsel on the question of the legality of the agreement, and we await with interest further developments.

SIGNALLING has been continued between the South Foreland and Wimereux during the week, and on Saturday last, amidst hail, snow and thunder storms, Mr. MARCONI received a deputation of Post Office officials, including Mr. LAMB, Mr. HOOKEY and Mr. GAVEY. As during previous experiments, neither the snow nor the hail in any way disturbed the transmission of messages, and a telegram was even successfully sent by Mr. LAMB during a thunderstorm. A deputation from the Amazon Telegraph Co. was present at these trials and expressed a determination of testing the system in Brazil. Additional experiments are being arranged to take place between Newhaven and Dieppe (64 nautical miles), between a cross-channel steamer and the shore, and between a French warship at different points in the Channel and the South Foreland. The United States War Department

Digitized by Google

has been conducting experiments between Washington and Fort Meyer. The Central News states that a proposal has been made in all seriousness, by the representative of a syndicate which wishes to acquire from the Wireless Telegraph Co., for the sole rights of establishing wireless telegraphic communication between England and America!

THE widespread interest which is being excited by all these experiments will no doubt lead to further trials on all sides, and it will be of advantage to bear clearly in mind the danger of interference alluded to in our last issue. Wireless telegraphy falls within the POSTMASTER-GENERAL'S monopoly, and no doubt his advisers see clearly that if licences were to be given to all who were willing to pay for them it would frequently be impossible to receive messages owing to the interference of other signals. In his letter to *The Times*, Captain BADEN-POWELL somewhat thoughtlessly appealed to the Post Office not to assert its monopoly against this method of telegraphing, but, unless there is a controlling authority, the use of the system on land will be practically impossible until the receiving of signals can be limited to the apparatus for which they are intended. Perhaps the most striking way to put this point is to say that any one, by installing, at the expense of a few pounds, a transmitting apparatus in the neighbourhood of the South Foreland and sending signals continuously, could paralyse MARCONI'S experiments to the Goodwins and Wimereux.

WE are able to give our readers the text of the first message transmitted between England and France by wireless telegraphy. It was sent by Mr. MARCONI from Wimereux, and, although certainly prosaic, fully answered the purpose for which it was intended. It ran thus:—"V V V Are you there V V V"

IN spite of the endeavours of the daily press, which are seconded in no way by the financial papers, the organs of probably the greatest users of the telephone, considerable discontent is being shown with the measure Mr. HANBURY is introducing in Parliament. Among the public bodies which have more recently passed resolutions disapproving of the Bill and in most cases favouring a general Government telephone service are the Liverpool City Council, the London and Liverpool Chambers of Commerce, and the Mersey Dock and Harbour Board. A long and interesting correspondence has also been published in *The Times* on the same question, and we would draw attention more particularly to letters from Sir JOHN LUBBOCK, who disapproves of monopoly whether owned by a company, Government or municipality; from Mr. FAITHFULL BEGG, who is an advocate of the Government taking over the whole business; from Mr. EDWARD RAE on the financial aspect of the question, and last, but not least, from Mr. F. E. BAINES, formerly Surveyor-General of the Post Office Telegraphs, the two latter also favouring absolute State control.

ALTHOUGH there were a number of telephone engineers present at the reading of Mr. GAVEY'S Paper on "Telephones" before the Society of Arts on Wednesday last, the greater proportion of his audience were representatives from the subscriber's end of the line, and the lecturer was well-advised in giving a simple and "popular" exposition of his subject, entirely avoiding technical and controversial matters. After briefly describing the telephonic receiver and transmitter, and touching on the advantages of metallic circuits over single-wire lines, he traced, in a few well-chosen words, the development of the telephone switchboard from the original "Umschalter" to the modern multiple board. He then waxed most eloquent over the very latest thing in switchboard design, viz., the central battery system, evolved by the Western Electric Co., of America. In this system, to which we have referred on previous occasions, the individual subscriber's batteries or magnets are replaced by one central battery at the exchange, serving both for ringing and speaking purposes, and, in addition, the calling and ringing-off is automatically performed by the removal of the subscriber's telephone from its hook and its subsequent replacement. Mr. SINCLAIR pointed out that a difficulty presented itself when a subscriber has more than one telephone in his establishment, but Mr. GAVEY prophesied a speedy solution. The National Telephone Co.'s exchange at Bristol is shortly to be equipped on this system, when it will have the practical trial in this country which it is already undergoing in the United States.

The other point chiefly emphasised by Mr. GAVEY was the large amount of labour involved in the erection of an exchange. Although to the subscriber who airs his grievances in the newspapers, and to the town councillor who thinks he could, himself, establish a better service, it may appear a matter of ridiculous simplicity to afford means of connection between the lines of any two subscribers, those who have technical knowledge of the subject know that the design and equipment of a large telephone exchange requires skill and experience by no means inconsiderable. To quote Mr. GAVEY'S words:—

> To take an analogy. It is a simple matter to provide the catering for a single establishment, but there are few problems of greater magnitude than the provisioning of an army of, say, 100,000 men. In the same way, any plumber-electrician can run up a few score wires and connect them to a switch, but when the wires grow from scores to thousands, and tens of thousands, spread over an area of some hundreds of square miles, the problem becomes as intricate as that involved in any other type of heavy electrical engineering.

MR. PREECE, who was in the chair, contributed the greater part of the discussion, alluding chiefly to what—to borrow a system of nomenclature now fashionable in other branches of electrical engineering—we may term the "grumble factor." This factor, it would seem, depends more on the education of the subscriber than on the efficiency of the system; in other words, the subscriber ought "to know better." One method of bringing this about, Mr. PREECE suggests, would be for the subscriber to visit an exchange and see for himself what the operators' duties are. We may mention that a most successful cure was recently administered in this way to our contemporary the *Financial News*. Mr. PREECE held up the Berlin subscriber as a pattern. In that city technically speaking, the service is one of the most backward, the lines being single-circuit, and the pattern of the instruments respectably antiquated. Yet the proportion of

Digitized by Google

inhabitants who are subscribers is large, and there appears to be no great dissatisfaction among them. But we may mention that every one of these subscribers has been trained to strict discipline, and is accustomed to obey orders and to bow down to Government officials. The punishment for calling a telephone operator a "sheep's head" may be imprisonment without the option of a fine; even the name of the offence is terrific, being a word of no less than sixteen letters. Assuredly all telephone officials will become advocates of compulsory military service and large standing armies.

The Royal Society Soirée.—The first of the two annual Royal Society soirées will be held on Wednesday, May 3rd.

The Soudan Telegraph Line.—A Reuter's telegram from Cairo announces that the telegraph is now open to Sennar on the Blue Nile.

Electric Lighting Bills.—The Central Electric Supply Bill and the St. James' and Pall Mall Electric Light Bill were read a third time in the House of Commons on Tuesday.

Cable Interruptions and Repairs.—

	Date of Interruption.	Date of Repair.
Paramaribo—Cayenne	Feb. 10, 1899 ...	April 10, 1899
Cayenne—Pinheiro	Mar. 10, 1899 ...	—
Maranhan—Para.....	April 10, 1899 ...	—

The Proposed National Physical Laboratory.—The London correspondent of the *Birmingham Post* announces that Government will ask Parliament for a grant of £4,000, to be continued for five years, and, as well, to make provision for a sum of about £12,000 for the erection of suitable buildings and laboratory equipment.

Patagonian Telegraphy.—The Argentine Government has, according to *Engineering*, invited Senor Luigi from Bahia Blanca for the purpose of discussing with him the construction of a telegraph line to Patagonia. The Argentine Government originally intended to build a land line, but opinion appears now to be inclined to favour the laying of a submarine cable.

The Paris Exhibition of 1900.—The Royal Commission for the Paris Exhibition of 1900 informs us that a Sub-Committee, consisting of the following gentlemen, has been appointed in connection with the British Electrical Section of the Paris Exhibition of 1900:—Mr. W. H. Preece, (Chairman), Sir Henry Mance, Mr. Alexander Siemens, Mr. Henry Edmunds, Mr. J. W. Swan, Mr. H. Thomson Lyon (secretary).

Obituary.—We regret to record the death on the 6th inst., at his residence in London, of Mr. F. L. Hutchins, in his 73rd year. Mr. Hutchins was a member of the firm of Murray, Hutchins and Stirling, and had a long connection with electrical matters through his position as legal adviser for the last 33 years to the India Rubber, Gutta Percha and Telegraph Works Co. Those who had relations with the deceased have lost an able counsellor and a sincere friend.

Accidents on the Continent.—The daily papers last Friday contained Reuter's telegrams, notifying two rather serious accidents in Switzerland and France respectively. At the electricity works in course of construction at Hagneck, on the Lake of Bienne, a dam, together with a caisson, was carried away by the River Aar. Of twelve workmen who were in the caisson at the time four were killed, while two were seriously and others slightly injured. In Nancy, the brake of an electric tramcar broke down while the vehicle was going down a hill. The vehicle dashed down the street at full speed, and collided at the bottom of the incline with another tram. Fourteen persons were slightly injured.

The Government Telephone Bill.—At a meeting on Wednesday of a joint committee of the Electrical and Allied Trades Section and Postal, Telephone and Telegraph Committee of the London Chamber of Commerce, appointed by the Council to consider what action the Council should take in connection with the Government telephone bill, the following resolutions were passed:—

1. "That this Committee recommends the Council to urge upon the Government that it is undesirable that the Postmaster-General should license the councils or county boroughs to provide systems of public telephonic communication, pending the report of the Joint Committee about to be appointed by the two Houses to consider the whole question of municipal trading."
2. "That the Council be recommended to urge upon the Government that, pending the Report of the Joint Committee to be appointed by the two Houses on municipal trading, the Telegraphs (Telephonic Communication, &c.) Bill should be postponed."

Royal Institution.—A general monthly meeting of the members of the Royal Institution was held on the 10th inst., His Grace the Duke of Northumberland presiding, on this the first general monthly meeting since his election as president. His Grace announced that the Hodgkins Medal, which is the first gold medal for scientific work ever given by the Smithsonian Institution, has been awarded to Prof. Dewar, of the Royal Institution of Great Britain, in recognition of his discoveries in the liquefaction of air, and in doing so he congratulated Prof. Dewar on this honour conferred on him, and also on the Royal Institution. He regarded it as specially gratifying as a sympathic recognition of scientific work and discovery in this country, coming from the great nation of our own blood on the other side of the Atlantic. The special thanks of the members were returned to Sir Benjamin Baker, K.C.M.G., for his donation of £50, and to Nobel's Explosives Co. for a donation of £105 to the fund for the promotion of experimental research at low temperatures.

Supply Interruptions.—Two recent failures of the electric supply at Hull are reported. The former, which affected the New Town section of the network only, occurred at 1:40 a.m. on the 30th ult., the cause being a short-circuit of the mains in the same street as on a previous occasion. Mr. A. S. Barnard, the borough electrical engineer, in his report to his committee, attributed the mishap to bad work on the part of the contractors. The supply being recommenced before six o'clock the same morning, no great inconvenience was caused. The second failure occurred about two o'clock on the 1st inst., and the whole supply was interrupted until 6:30. The cause appears to have been a too sudden switching-on of a large motor used in the *Eastern Morning News* printing office, thus reversing one of the 110 volts dynamos then running. The long delay in re-establishing the supply was due to the fact that half of the storage battery at the works was disconnected for repairs.—An accident which occurred at the Port Adelaide electric light station on Feb. 9 is reported by mail. It is particularly unfortunate, as the station in question had only been running for a few days. Soon after the engines had been started for the evening, the main steam-pipe, connecting one of the boilers with the engine-room, burst close to the expansion joint. Fortunately a very small load was on, and the stop valve was open barely a quarter of a turn, so that in spite of the darkness the steam was shut off without great difficulty. The broken length of pipe was thrown with considerable force against the wall of the boiler-room, but no one appears to have been injured. There being no spare lengths of steam main available, the station was obliged to shut down for a few days.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, April 14th.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Earth Currents and Electric Traction," by Prof. A. W. Rücker.

WEDNESDAY, April 19th.

ROYAL METEOROLOGICAL SOCIETY.

7:30 p.m. Ordinary Meeting at 25, Great George-street, S.W.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Meeting at 20, Hanover-square, W.

THURSDAY, April 20th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Special Meeting, when Prof. J. A. Ewing, F.R.S., will deliver the seventh "James Forrest" Lecture, the subject of which will be "Magnetism."

Digitized by Google

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Wehnelt's Electrolytic Interrupter.—H. Pellat throws some further light on the curious phenomenon noticed by him (*see The Electrician* of April 7, p. 822) by an observation which shows that the strong and the feeble current intensities obtained with the same resistance, according to the impedance in the circuit, are convertible, and only differ in stability. With an E.M.F. of 110 volts and the coil in position, the current strength is 25 amperes, the long flame plays between the terminals of the secondary and the interrupter makes a good deal of noise. On short-circuiting the primary, the current falls to five amperes, but not till several seconds have elapsed. The interrupter is then silent. On reintroducing the impedance, the strong current is not necessarily re-established. Often there is no difference, but a kind of chirping noise in the interrupter. But if the commutator of the coil is opened and closed, the strong current and long flame at once set in again, and the interrupter hums. This shows conclusively that of the two explanations proposed, the second is the correct one, and that the impedance introduced modifies the ratio of the open to the closed time, or more precisely, the quantity

$$\frac{E}{T}\int_0^T \frac{dt}{R}.$$

[Pellat, *Comptes Rendus*, March 27, 1899.]

Properties of Uranium Rays.—H. Becquerel has repeated some of his earlier experiments on the rays named after him, and has found that the conclusions originally derived from them were to a great extent erroneous. As a matter of fact, it cannot be proved that these rays, whether proceeding from uranium, thorium, polonium, or radium undergo either polarisation, refraction, or regular reflection. The absence of these properties places them on a line with Röntgen rays. There are some distinct indications of diffused reflection, and there again the analogy with X-rays holds good. As regards absorption, it is found that polonium gives out rays which are easily absorbed, even by black paper, whereas radium and uranium rays have much greater penetrative power. As regards the source of the energy of these rays, the author still considers that an open question. Even when kept beyond the reach of any known radiation for three years, these substances still give out rays capable of impressing a photographic plate and of ionising the air. It has been suggested that they undergo some internal process which leads to the radiation of energy, and as the latter is very small, such radiation could be kept up for very long periods. But that is unlikely, since no known physical process is capable of increasing the energy thus given out.

[Becquerel, *Comptes Rendus*, March 27, 1899.]

Slow Oscillations.—Some elegant new methods of studying oscillating discharges have been devised by W. König. They are based upon the well-known phenomenon of Lichtenberg's figures, and are applicable to all oscillations of periods not exceeding those of ordinary sound-waves. He uses a metallic plate painted with asphalt lacquer and attached to a pendulum. The discharge is conducted to the plate through a conductor provided with a tip of straw, thus reducing the spreading of the figures. Well defined red and yellow lines are thus obtained, when the plate is strewed with a mixture of red lead and sulphur. The method may be further improved by attaching the straw to the prong of a tuning-fork. Every section of the wavy line obtained then represents a reversal, and the number of waves in each section is a measure of the period of the discharge. The method is extremely accurate as such measurements go, the errors not exceeding 1 per cent., and it is available down to 20 volts. The author has applied it to verify the theoretical laws of discharge, and especially the influence of an iron core. When that is present, the period greatly alters with the amplitude, but as the frequency increases, the influence of the iron core becomes less and less marked.

[König, *Wied. Ann.*, No. 3, 1899.]

Demonstration of Wire Waves.—When the parallel wires of the Lecher system are led through long vacuum tubes, as proposed by Arons, the tubes light up along their whole length on working the exciter. But if the wires are bridged both in front and behind the tubes, in such a manner that the distance between the bridges is a multiple of half a wave-length, stationary waves are formed along the wire, indicated by the luminosity of the sections, and the darkness at the nodes. W. D. Coolidge has now succeeded in reproducing the same phenomenon in the open air, and with waves only 12cm. long. This was done by increasing the amplitude of the oscillations and by reducing the diameter of the parallel wires to 1mm. or even 0·1mm. The author used a Blondlot exciter immersed in petroleum. The secondary circle was just below the primary, and only separated from it by a plate of mica. The source of energy used was an induction coil provided with a Tesla transformer. The distance between the parallel wires was 1 or 2cm. On darkening the room the wires were seen to glow at the ventral segments, and some capital photographs were obtained.

[Coolidge, *Wied. Ann.*, No. 3, 1899.]

Consumption of Energy in Vacuum Tubes.—H. Ebert has measured the energy dissipated in vacuum tubes fed, not with a continuous, but with an alternating current. Direct-current measurements cannot be applied to this case on account of the phase difference introduced by the capacity of the discharge tubes. He carried the measurements to very high vacua, and made the important observation that the higher the vacuum the less the energy consumed in proportion to the luminous effect obtained, especially with the high potentials (3,000 volt) and the high frequencies employed (22,000 ∿ per minute). At a certain point, however, the consumption of energy attained a minimum, after which it rose again on further increasing the exhaustion. This "pressure of reversal" has a simple relation to the mean free path of the gas in the tube, being, in fact, inversely proportional to it. The further conclusion arrived at is that where the molecular diameters are equal the reversal pressure is the higher, the smaller the number of valencies in the gaseous molecule, *i.e.*, the fewer the ionic charges which are liberated on complete dissociation. A gas offers the greater resistance to discharge the higher the valency and the smaller the sphere of influence of its molecules.

[Ebert, *Wied. Ann.*, No. 3, 1899.]

ALEXANDER PELHAM TROTTER.

We are glad to announce that Mr. A. P. Trotter, the Government Electrical Engineer and Inspector for Cape Colony, has been appointed electrical adviser to the Board of Trade, in succession to Major Cardew, whose resignation we recently recorded. We feel sure that all our readers—even those who do not know him personally—will echo our congratulations to Mr. Trotter, and welcome his return to this country, as he was for five years their "guide, philosopher and friend" during the period he occupied the position of editor of *The Electrician*. Major Cardew, whom he is to succeed at the Board of Trade, having carried out his duties with such extreme ability and tact, the task for his successor must necessarily be no easy one, but we cannot imagine a man better suited to undertake it than Mr. Trotter.

Mr. Trotter is an old Harrovian. At Harrow he was most distinguished by his being the best swimmer and diver; and, subsequently, at Trinity College, Cambridge (where he went, after a few months at King's College, London) he was as successful as an athlete as in reading, for he took Honours (Second Class) in the Natural Science Tripos, having studied under Clerk Maxwell, Prof. Michael Foster and Prof. J. Stuart, and yet found time to be captain of the Cambridge Bicycle Club, and to lower several records in bicycle racing: he was the first to accomplish one mile in less than three minutes. In 1880 Mr. Trotter articled himself to Messrs. Easton and Anderson, of Erith, and in 1884 he was engaged by the War Office on the design of electric search-lights, and also

Digitized by Google

assisted Mr. Preece in photometric tests of street lighting. His next engagement was with Messrs. Edmunds and Goolden, and about this time some may remember his lectures to evening classes at King's College. Subsequently he entered into partnership with Mr. W. T. Goolden, and the works of Messrs. Goolden and Trotter were built at Halifax. In 1887, not caring for the commercial part of the business, Mr. Trotter dissolved partnership, and returned to London to practise as a consulting engineer. In April, 1889, in addition to his consulting work, he fulfilled the duties of Technical Secretary to the Electrical Trades' Section of the London Chamber of Commerce, and in 1890 became editor of *The Electrician*. Since the beginning of 1896 Mr. Trotter has been in Cape Town as Advisor to the electrical Government, and has been doing a vast amount of useful work there. Mr. Trotter is forty-one years of age. Space will not allow us to give a full list of all the Papers he has contributed to scientific and engineering societies, but we may mention, among the more important, one read before the Institution of Civil Engineers on "The Distribution and Measurement of Illumination;" several others on similar subjects and on the physics of the electric arc, and the interesting account of his investigations of the disturbances caused in the submarine cables in Cape Town by the working of the electric tramways there. The latter, it will be remembered, formed the substance of a Paper, which received the honour of an extra premium by the Institution of Electrical Engineers, in 1897. Mr. Trotter has also been to the front in his advocacy and development of graphical methods and in everything pertaining to the slide rule.

CARBONS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.*

BY FRANCIS JEHL.

VIII.—ESTIMATION OF HIGH TEMPERATURE.

Among carbon manufacturers, the ordinary parlance, when referring to the temperature at which they bake their carbons, will generally be found similar to that used in the pottery industry, that is, designated by Prof. Seger's pyramids. It is a well-known fact to pottery manufacturers that it was formerly a very difficult thing for them to estimate in a practical way the temperature at which they had to bake their goods. To use pyrometers, no matter of what design, generally required some skilled attendant, while at the same time the readings of such instruments were often misleading.

At the request of a well-known "Chamotte" works in Germany, Prof. Seger made a series of exhaustive experiments to determine the different points of fusion of certain mixtures of pure silicates, &c., which he moulded into the shape of small blunted pyramids. In fact, the Seger pyramids represent a series of systematic mixtures, each of which have a different point of fusion, varying 20°C to 30°C from one another. Thus one set of the Seger pyramids that is numbered from 0·22 to 0·10 can be used to estimate temperature that lies between 590°C to 950°C respectively, there being a difference of about 30deg. between each successive number in regard to its point of fusion. Another set, numbered from 0·9 to 1·0, is used for temperatures varying from 970deg. to 1,130deg., while each succcessive number's point of fusion varies by 20deg. A third set, 1 to 36, is used for temperatures between 1,150°C and 1850°C respectively, each successive number's point of fusion varying also by 20deg. Thus, by means of the 58 pyramids, any temperature between dull red and the melting point of platinum can be estimated. When a carbon manufacturer, therefore, says he uses a No. 17 or 18 Seger pyramid in his Mendheim furnace, he means that he bakes his carbons at an estimated temperature of about 1470°C or 1490°C respectively.

It must be understood that this mode of measuring temperature is not to be taken as scientifically correct, but in practice it has been found to suit all requirements and the estimation of heat obtained by such means has enabled the pottery industry (as well as the carbon trade) to burn or bake their goods with a precision heretofore unknown. The above table* gives the numbers, chemical composition and the estimated temperature at which the pyramids most commonly used by carbon makers fuse, or rather fall over, when subjected to a certain heat.

Pyramid number.	Chemical composition.	Estimated temp. Degs. Centigrade.
10	$\left.\begin{matrix}0{\cdot}3\ K_2O\\0{\cdot}7\ CaO\end{matrix}\right\}$ 1·0 Al_2O_3 10 SiO_2	1,330

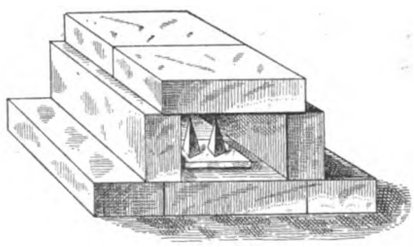

FIG. 53.—Method of Protecting the Pyramids.

It is usual to place the pyramids (two or three successive numbers) in two different parts of the furnace so as to be able to get a good idea of how the heat is distributed, and not to turn off the gas until all parts of the chamber have an even temperature. It is, of course, understood that the pyramids should be protected from the direct action of the flames, as otherwise erroneous results are obtained.

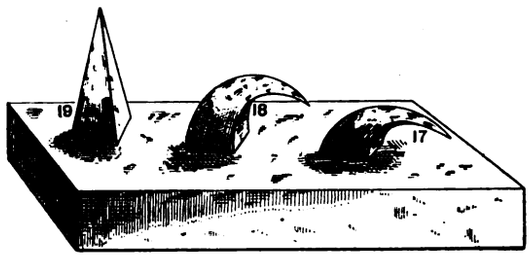

FIG. 54.—Seger Pyramids in the Furnace.

The best way to place the pyramids in the furnace is to protect them by some fire-bricks, as shown in Fig. 53, and at the same time they must be so placed that they can be seen from the peep-holes of the furnace. These peep-holes are generally covered with mica, to prevent the air from getting in when observations are made, which when not in use are covered with fire-bricks. In using three successive numbers of the pyramids at a time for observation we have a convenient way of noticing the rise in heat, and Fig. 54 will serve to show how the estimation is approximately judged and fixed. Here we have the three pyramids—17, 18, 19—that have already been subjected to the action of a furnace. We see that 17 is fused down, and conclude that the temperature

* For a detailed account of Prof. Seger's pyramids, *see* pamphlet published by the *Thonindustrie Zeitung* (Berlin).

Digitized by Google

that existed must have been higher than 1,470deg. Pyramid 18 is pretty well bent over, and we can thus estimate that the intensity of the heat must have been very near to 1,490deg. That the temperature did not reach as high as 1,510deg. is proved by the fact that pyramid 19 is still straight..

It will be seen that the whole method of observation is a very simple one, and that any common workman can be entrusted with it. It may be mentioned that the pyramids should always be placed in the same place in the furnace, so as to always get the same relative results. When the pyramids have once been used they are not good for a second time, and new ones are thus always placed in the furnace with each charge. As they are very cheap, this is a matter of no importance. To prevent the pyramids from falling over, it is usual to use a little fire-clay and paste them at their base on to the fire-brick.

IX.—THE MANUFACTURE OF ELECTRODES ON A SMALL SCALE.

The financial success of many electro-chemical or smelting works is often dependent upon the cost of the electrodes they employ, which in most cases are made from carbon. It would, no doubt, be to the interest of such concerns to manufacture their own electrodes, and the following estimate will give the approximate costs of a small plant that can produce about 500 kilos. (1,100lbs.) of electrodes per day, or 3,000 kilos. (6,600lbs.) per week.

In the following estimate a Braun hydraulic press, No. 3, is taken, which can squirt electrodes having a width up to 180mm. (F″). If larger sizes are required than the above, a Braun hydraulic press, No. 5, must be employed, which can produce electrodes having a width up to 500mm. (19·5″). Such a press would increase the cost of the plant about £541. 6s. = $2,600 = fl.6,500.00. Press No. 3 can work off about 1,300 kilos. (2,860lbs.) per day, and press No. 5 about 13,000 kilos. (28,600lbs.) We see thus a press in a plant that only makes about 500 kilos. (1,100lbs.) works only a few hours every day.

It may also be mentioned that in the following calculations the price of the raw material (common mixture, Table B and D) is taken at fl.0.05 (1d. or 2.5cts.) per kilo., and the material consists of either petroleum coke, or gas retort carbon mixed with tar. However, in many cases common coke, as obtained at any gas works, is just as suitable for making electrodes, while its cost is less than half. Works that produce carborundum, calcium carbide, or aluminium, &c., will find that electrodes made of common coke will answer their requirements. It is well when buying the coke to pay a little more per ton, and have only dense pieces picked out, which are better suited for making electrodes. In the estimate the writer has taken the low figure of fl.0.20 (4d. or 8cts.) per kilo. as the cost of the finished electrodes, although it is not probable that any concern can buy their electrodes at such a low price.

It is supposed that power is at hand (about 10-12 H.P.), also a small space where the machinery can be set up, and for both an item of rent will be inserted in the yearly expenses.

Sundries	270.00	22 10 0	108.00
	fl.15,300.00	£1,275 0 0	$6,120·00
Capital invested in electrode plant	fl.26,000.00	£2,166 13 4	$10,400.00
Working capital put in	10,000.00	833 6 8	4,000.00
Total capital considered as invested	fl.36,000.00	£3,000 0 0	$14,400.00

1,100lbs. = 500 kilos. electrodes per day is about 330,000lbs. = 150,000 kilos. per year.

At the low price of 4d. (8cts. or fl.0.20) per kilo. (2.2lbs.) we have :—

$\frac{330,000}{2.2} \times 4 = £2,500$, or $\frac{330,000}{2.2} \times 8 = \$12,000$, or $150,000 \times .2 = fl.30,000$.

Raw mixture at 1d. = 2cts. = fl.0.05 per kilo :—

$\frac{330,000}{2.2} \times 1 = £625$, or $\frac{330,000}{2.2} \times 2 = \$3,000$, or $150,000 \times .05 = fl.7,500$.

Expenses per year	£1,275.00	$6,120.00	fl.15,300.00
Raw material	625.00	3,000.00	7,500.00
Total	£1,900.00	$9.120.00	fl.22,800.00
Price of electrodes	£2,500.00	$12,000.00	fl.30,000.00
Expenses	1,900.00	9,120.00	22,800.00
Profits	£600.00	$2,880.00	fl.7,200.00

This shows that when electro-chemical works or smelting concerns make their own electrodes, they can produce them at about £1. 13s. 4d. = $8.00 = fl.20.00 per 100 kilos. (220lbs), and yet have a profit on the money they invest, or, in other words, they can produce their electrodes at less than £1. 13s. 4d. = $8.00 = fl.20.00 per 100 kilos., when they desire only an interest of 5 per cent. on the capital they invest.

In carborundum works there is a by-product of good carbon which will make excellent electrodes, so that such concerns have at hand a very cheap raw material which can be considered as costing them hardly anything. It is self-evident that when a works needs more than about 500 kilos. (1,100lbs.) of electrodes per day, the cost of manufacturing will not increase proportionally, as the more they make the cheaper will be the price of production per kilo., up to a certain limit. The writer has calculated, for instance, that when a carbon works invests about £600 ($2,880 or fl.7,200) for an electrode plant that can produce about 4,000 kilos. (8,800lbs.) per day, electrodes can be produced at about £1. 5s. ($6 or fl.15.00) per 100 kilos., and at which price there will still be a profit of about 25 per cent. to 30 per cent. on the capital invested.

The main success in all enterprises is, of course, largely dependent upon the amount of goods that will be sold, which amount cannot with certainty be fixed beforehand, yet the writer is of an opinion that the carbon industry would thrive well in England, while in the United States high grade carbon factories must, under all circumstances, prosper, as there is a growing demand for such brands. The fact that Europe has been sending large quantities of carbons, &c., to the above mentioned countries is enough to warrant the establishment of such works. A carbon factory, as has already been mentioned should have its own soot works, and thus obtain a greater margin in its profits, as soot can no doubt be produced at about 20-30 per cent. less than the price the writer took in his calculations.

Having a soot factory, printers' inks can also be made, as done by a carbon factory in Austria. Shoe blacking, crucibles,

Digitized by Google

water filters, and other articles, the manufacture of which are all sister branches to the carbon industry, afford an extension in business that will help to swell the profits by investing a little extra capital. As carbon factories have good furnaces, there is no reason either why they should not make their own retorts in which the carbons are baked or carbonised, which will thus also cut down some of the yearly expenses. Only one or two extra machines are necessary for the purpose, by which the broken retorts are ground up, and, with an addition of some fireclay (chamotte flour), new retorts can be moulded or pressed and baked in the same furnace in which the carbons are placed if there is room, or when business is slack. The broken retorts furnish a very favourable material, as they have been subjected to high heat.

(To be concluded).

EXPERIMENTS ON ALTERNATE-CURRENT ARCS BY AID OF OSCILLOGRAPHS.

The Paper which, under the above title, has just been presented by Messrs. W. Duddell and E. W. Marchant to the Institution of Electrical Engineers, forms one of the most valuable contributions to our experimental knowledge of the alternate-current electric arc which have yet been published. The communication is printed in full in No. 138 (Vol. XXVIII.) of the *Journal*, of which it fills no less than 107 pages. Not only has the investigation a value intrinsic to the particular conditions of alternate-current working, but, as we have before observed, we think that a careful study of the alternating, as compared with the continuous-current arc, is likely to prove as fruitful, if not more fruitful, of that experimental evidence and subsidiary phenomena which will ultimately lead to an explanation of the whole collective phenomenon. In view of the impossibility of reproducing the whole of this voluminous Paper, it is hoped that the following abstract will present some of the more important results which the investigation has developed.

The Paper commences with a very useful little bibliography of the published literature bearing on the subject of the investigation, which may be said to be a general examination of the reaction which an arc has long been known to exercise on the wave form of the alternate current in the circuit. Thus, if a non-inductive resistance between two points in an alternate-current circuit be replaced by an arc, the current wave and the wave of potential difference between these two points will be modified, although the arc transmit the same virtual or "root-mean-square" current at the same potential difference. This modification which takes place in the wave forms, depends upon the nature of the carbons employed, the nature of the rest of the circuit, frequency, length of arc, &c. The authors thus remark :—

In an investigation like the present into the reactions of the alternate current arc on the wave form, we in general require three wave forms, viz. :—

1. The form of the wave of potential difference between the terminals of the dynamo when the arc is burning (which we will call for short the "P.D. dynamo" curve).
2. The form of the wave of potential difference between the terminals of the arc (which we will call the "P.D. arc" curve).
3. The form of the wave of current (which we will call the "current" curve).

We also require the root-mean-square values of the above waves, the power supplied to the arc, the arc length, and the data of the circuit in which the arc is burning. It is preferable, and in many cases absolutely necessary, that the corresponding wave forms of the different electrical quantities, *i.e.*, P.D., current, &c., should be obtained simultaneously. Many of the most interesting phenomena of the arc and those on which we require additional information are of a more or less variable or transient nature, such as the hissing arc, and arcs between electrodes other than carbons, consequently the waves only repeat themselves a very limited number of times, if at all.

These considerations led us to choose a method in which the time taken in recording each wave is as small as possible, and by which the several P.D. and current wave forms can be obtained simultaneously.

A description of the oscillograph used was given in a Paper on "Oscillographs" before the British Association at Toronto.* The arrangements permitted of a photograph being taken at any moment, such as when the wave-form, as viewed directly by the eye, was seen to be representative of the general form under the particular conditions. The connections generally used were :—In the main circuit of the alternator was included (in series with the arc) a non-inductive resistance or impedance coil, as the case required. Also, in series with the arc was a resistance of 0·1 ohm, across which that coil of the double oscillograph for recording the current wave was connected. The other coil of this oscillograph was connected across the terminals of the arc, and recorded the pressure wave of the arc. An Evershed alternate-current ammeter and a Ganz wattmeter enabled the current through and the power taken up in the arc to be measured. An Ayrton-Mather electrostatic voltmeter permitted either the alternator potential difference or the pressure across the first-mentioned resistance or impedance coil to be read. Finally, a reflecting electrostatic voltmeter indicated the potential difference between the lamp terminals. A single oscillograph connected across the alternator terminals recorded the alternator pressure wave. Then follows an account of the experiments :—

We must call attention here to the fact that we measured the P.D. between the terminals of the lamp and not between the tips of the carbons, therefore what we call "P.D. arc" includes the drop of pressure in the terminals, the metal work of the lamp, the carbon holders, and two 10cm. lengths of carbon, 10cm. being the length we usually allowed to project from the holders. We determined experimentally, by short circuiting the carbon holders with a 20cm. length of carbon, what this drop amounted to, and found that, with our ordinary working current of 14·8 amps. and all the metal work hot as in use, the drop was 1·15 volt, and thus the resistance of these contacts, &c., is 0·078 ohm. All the figures which we give later are the actual readings and are *not* corrected for this drop.

Two alternators, which differed very greatly from each other, were used for our experiments :—

1. A Ferranti alternator of 9 kw. capacity which had a small armature reaction and which gave on open circuit, or on a non-inductive resistance, a very close approximation to a sine wave ; this machine had a range of frequency from 90 to 240 ∿ per sec. and gave at 100 ∿ per sec. on open circuit with maximum excitation about 100 volts.

The resistance of the armature is 0·24 ohm.
The self-induction „ „ 0·0009 h.

2. A Pyke and Harris inductor alternator* of 6 kw. capacity which had a very large armature reaction and which gave on open circuit a peaked wave form, and on a non-inductive load a kind of hump. This machine had a range of frequency from 30 to 125 ∿ per sec. and gave at 100 ∿ per sec. on open circuit with maximum excitation about 330 volts. The resistance of the armature is 0·4 ohm. The self induction of the armature, which is very large, varies with the exciting current and position of the inductor from a maximum with no excitation and the inductor opposite the pole of 0·012 henrys to a minimum with the maximum exciting current we have used, and the inductor half-way between the poles of 0·009 henrys.

The arc lamp used was a hand-regulated one, having adjustments for centreing the carbons, and fitted with holders for two search carbons. For the purpose of measuring the length of the arc its image was projected on a screen by means of a lens so placed that the image was six times as large as the arc ; the screen was ruled with lines 6mm. apart, so that the length of the arc could be read off direct in millimetres. And it is the length as measured on this screen which we mean when we speak of the length of the arc ; thus, for example, length 0·0mm. does *not* mean that the *carbons* were actually *touching*, but that the *images* of the carbons were *touching*.

Plan of Experiments.

In every experiment, a certain length of arc and current having been selected, the speed and excitation of the alternator were kept constant, and *the distance between the carbons was regulated so as to keep the P.D. between them constant during the whole course of the experiment.*

When once the arc had burnt into shape—that is, had attained the steady state corresponding with the length, current and other conditions under which it is burning—we found, as long as the conditions of the dynamo and circuit remained the same, that regulating the length of the arc so as to keep the P.D. between its terminals constant, maintained the arc length, the current and the power supplied to the arc constant. Thus it is possible to compare our results with those of M. Blondel, who kept the current constant, and those of Prof. Fleming, who kept the power supplied constant. Mrs. Ayrton has drawn attention to the fact that, with the direct-current arc, a considerable time is required for it to attain a steady state, and we find that this, as might be expected, applies equally to the alternate-current arc.

We have had considerable difficulty in obtaining even approximately comparable results when using an arc with one or both of its carbons cored ; this difficulty, which we believe was also first pointed out by Mrs. Ayrton, seems to be due to a want of uniformity in the composition of the core and in the binding material which holds the core together. There are two kinds of carbons in general use—namely, solid and cored—and these give three combinations between which we can burn an arc, and they are :

1. The arc between solid carbons, which we will call, for the sake of shortness, the "solid arc" ;

2. The arc between one solid and one cored carbon, which we will call the "solid-cored arc," always putting the top electrode first; and

3. The arc between two cored carbons, which we call the "cored arc."

In most of our comparative experiments we have used one make of carbons throughout—namely, the "Apostle"—and we have tried in turn the effects with the "solid," the "solid-cored" and the "cored arc" with carbons of this make.

In the diagrams and tables corresponding numbers in each refer to the same experiment, the number of the experiments in the diagrams being given in the right-hand bottom corner of each set of wave forms. In the wave forms given in the diagrams time is always measured from left to right, as usual, and the scales of the respective curves are given on each diagram as so many volts or amperes per millimetre. Also in all cases the top half of the wave form corresponds to the top electrode being positive.

Section 1.—Preliminary Experiments.

(Fig. I and Table I.)

To give a clear idea of the main features of the reaction of the arc on the alternate current wave forms, we replaced a non-inductive resistance, between two points in a circuit, by a solid arc taking the same r.m.s. (root-mean-square) current, while the dynamo excitation and the other conditions of the circuit remained unchanged. The results of this substitution, for three different circuits, are given in the first two rows of Fig. 1. In each case the arc substituted had the same length, carbons, and current.

In the first case the whole circuit, including the alternator, was comparatively non-inductive, and with resistances alone all the waves were sinusoidal (experiment 1). The substitution of the arc for part of the non-inductive resistance caused a flattening of the P.D. wave between the terminals of the resistance, the production of a large front peak p, and the reduction of the current to zero for a considerable portion of the period (experiment 2).

In the second case, in which some of the resistance was replaced by inductance (experiment 5), the P.D. arc curve is almost rectangular, while the current rises nearly as rapidly as before the arc was introduced (experiment 6).

In the third case, the total inductance in the circuit had approximately the same value as in the last; but instead of having inductance outside the alternator an inductive machine was used. Although before the introduction of the arc the P.D. and current curves (experiment 9) are quite different from those previously obtained, yet after the substitution the P.D. arc curve is nearly rectangular, as before; but the current wave is little affected by the change (experiment 10).

In row 4, two cored carbons are employed; and although, to keep the arc conditions constant, it was necessary to change the dynamo excitation, the curves are comparable in *form*, respectively, with those in the first row obtained with resistance in place of the arc. It will be noticed that the current curves in row 4 are practically the same as those in row 1, but that there is a characteristic dent, d, on the front side of the P.D. arc waves (experiments 4, 8, 12). It might be expected that the solid-cored arc would have a reaction intermediate between those of the solid and the cored arcs, and this is the case, the P.D. arc waves, row 3, being squarer in shape than those in row 2. But, further, the two halves of the P.D. wave, above and below the zero line, are not exactly the same; the top half, which corresponds to solid carbon +, being slightly convex to the axis of time as in row 2, while, on the other hand, the lower half, which corresponds to the cored carbon being +, shows, especially in experiment 3, the characteristic dent of the cored P.D. arc curve. *Hence it follows that the nature of the positive, at any instance largely governs the reaction at that time*, and this conclusion is amply borne out by experiments to be described later.

There is an observation of M. Blondel which is illustrated by Fig. 1, and which impresses itself on us the more we work at the subject, and that is, that the shape of the P.D. arc wave depends on the total resistance and self-induction in the circuit (including the alternator armature) and is almost independent of the type of machine used, whereas the current wave form is largely dependent on the machine used and the nature and amount of the impedance of the circuit.

When for a resistance between two points in a circuit we substitute a solid arc taking the same R.M.S. current, and the dynamo excitation and other conditions remain unaltered, we find that the R.M.S. of the P.D. between these points is raised in all cases (experiments 1 and 2, 5 and 6, 9 and 10, Table I.). The power supplied to the circuit between the two points is greatly reduced by the substitution of a solid arc for one of the two resistances in series with the Ferranti alternator (experiments 1 and 2); and as the R.M.S. current has not been changed, the power supplied to the circuit outside the arc is constant, therefore the whole output of the alternator is reduced by replacing part of the outside resistance by a solid arc, the main current and the excitation, &c., being the same in both cases. We arrive at a similar conclusion when we consider an inductance and a resistance in series with the Ferranti machine, the resistance being replaced by a solid arc taking the same current (experiments 5 and 6); in this case, however, the effect is only slight.

With the third circuit—that is, a large and small resistance in series with the inductive Pyke and Harris alternator—the replacing of the larger resistance by a solid arc taking the same current (experiments 9 and 10), the other conditions remaining the same, leads to an increase of the output of the machine, which is the opposite to the effect in the last two cases. An examination of the wave forms (experiments 1 and 2) shows that the reduction in output on the Ferranti alternator is due to the current remaining small during a considerable portion of the period while the P.D. is comparatively large, and in a less degree to the drop in the P.D. dynamo which accompanies the higher maximum value of the current. This also explains the slight reduction observed in experiments 5 and 6. The observed increase of output of the Pyke and Harris alternator is not so easily explained, for the total self-induction of the circuit in experiments 9 and 10 is roughly the same as in experiments 5 and 6. The explanation,

however, seems due to the fact that, owing to the very large internal drop of pressure in this machine, a slight diminution in the current at any instant is accompanied by the large increase in the P.D. between the dynamo terminals. With the solid-cored and cored arcs the effects are similar; but all occur in a much less degree.

The R.M.S. value of the P.D. between the terminals of the alternate-current arc, the power it absorbs and its power factor are not fixed functions of the nature of the carbons, the arc length and the current, but depend also on the nature of the circuit outside the arc. Thus, with the solid arcs (experiments 2 and 6), which are between the same carbons, have the same length and R.M.S. current, and are supplied by the same alternator, the P.D. between the terminals of the arc is reduced 3 volts, or 6 per cent., if resistance in series with the arc be replaced by self-induction, while at the same time the power absorbed by the arc is increased by 9 per cent., with a consequent improvement of the power factor from 0·74 to 0·855. The same effect is also produced if, instead of self-induction in series, a highly inductive alternator supplies the arc (experiment 10). With solid-cored and cored arcs the same changes occur, but to a less extent. The power factors of solid-cored and cored arcs are always higher than those of solid arcs, and for the cored arc are generally very close to unity.

One of the most striking results we have obtained is the great stability and comparative silence of all the arcs we have tried on the inductive Pyke and Harris machine, coupled with their steadiness and high-power factors. We think that, *if a highly inductive alternator, having good efficiency and a steep characteristic, could be built, these machines would be eminently suitable for arc lighting. For then the necessity for choking coils would vanish, and harder carbons, giving, therefore, a much higher luminous efficiency, could be employed without loss of steadiness of the light.*

Fig. 3.—Effect of Length of Arc.

Section 2.—Effect of Length.

(Figs. and Tables II. and III.)

In order to test the effect of the arc length on the reaction on the wave form, the size and kind of carbons, the current through the arc, the resistance, &c., in series, and the frequency of the impressed E.M.F. were kept constant, while the arc length alone was varied, the current being kept at the same value by changing the dynamo excitation.

With the solid arc on the Ferranti alternator, length 0mm. (experiment 13), the P.D. arc curve has two small peaks connected by a slightly wavy* horizontal portion which we find is characteristic of the sound which the arc produces, the current remaining small for about one-eighth of the period. If we now lengthen the arc, keeping the R.M.S. current through it constant, we find the front peak p on the P.D. arc curve grows higher and higher, while the back peak and waviness in the horizontal portion do not change much, until we reach an arc length of 1mm. (experiment 14), which is a steady hissing arc; in this curve the length of time during which the current remains small has increased to about one-fourth of the period, and has caused the power factor to drop to the low value of 0·63. On still further increasing the length of the arc the peak on the P.D. arc curve no longer increases rapidly, and the time during which the current is small remains about the same (*see* experiment 15), which was with an arc length of 3mm. Experiments 19, 20,* 21 and 22 are with the cored arc. In this case the characteristic change in the P.D. arc curve is that the dent d occupies a relatively higher position up the side of the curve as the arc length is increased. The results with the solid-cored arc (experiments 16, 17 and 18) are much more complicated.

On the inductive Pyke and Harris machine, owing to its higher E.M.F., much longer ranges of arc lengths were obtainable, being only limited by the instability of long arcs. Thus, with the solid arcs on this machine, we were able to obtain a range of lengths from 0mm. to 20mm. (experiments 23 to 28†). In this experiment, as with the solid arc on the Ferranti dynamo, the front peak in the P.D. arc curve increases with the length, but in a more regular manner, while the second or back peak is hardly noticeable when the arc length is more than about 10mm. The current wave form tends to become more triangular in shape as the arc length increases; but this effect, we think, is due to the increase in excitation of the alternator, and not to the change in length of the arc itself, as this machine gives, when sending current through a non-inductive circuit, a more triangular wave when the exciting current is increased.

The effect of change of length with the solid-cored and cored arcs on this machine is illustrated by experiments 29 to 41,‡ the dent d moving up the side of the P.D. arc curve with cored carbons as before, and finally forming a front peak for long-cored arcs. The P.D. arc curve of long solid-cored arcs also has a high front peak.

A point of interest, as measuring in a way the stability of the arcs, is the length at which each arc could be burnt, the frequency, the resistance in series and the arc current, all remaining the same, the corresponding lengths being 20mm. for the solid arc, 30mm. for the solid-cored, and 45mm. for the cored arc. The power factor, in all cases, on both alternators is lowest for hissing arcs, and generally increases with increase of arc length. With solid carbons, however, we find that the power factor has a minimum in our experiments, when the arc length is about 1mm., and the arc is hissing steadily.

In all the long arcs we have tried, whether with solid or cored carbons, we find that the P.D. between the terminals of the arc rises rapidly to a high value after passing through zero, and then falls again almost at once, forming a front peak on the curves. The increase in height of this peak, with increase of arc-length, led us to think that it was connected with the resistance of the gaseous column forming the arc proper, and we, therefore, tried the experiments described in the next section to settle this point.

(To be continued.)

THE INDUCTION MOTOR.*

BY ERNEST WILSON.

(Concluded from page 827).

Armature Reaction.

Before dealing with the armature or secondary circuit of this motor, it will be well to examine the disturbance produced in the primary induction, as the external resistance ρ is varied from ∞ to zero. The inductions $m_1\int\frac{dI_1}{dt}dt$, $m_2\int\frac{dI_2}{dt}dt$ give the average over a half period $\theta/_2$, and are plotted in Figs. 8 and 9 respectively for values of $\rho=\infty$, 1·07, 0·149 and 0·0095, the frequency being 95 periods per second. It will be seen that the disturbance is not great; it is greatest when $\rho=0{\cdot}0095$. The variation of this average induction for $\rho=0{\cdot}15$ at 52 periods per second can be seen by comparing Table IV. with III.

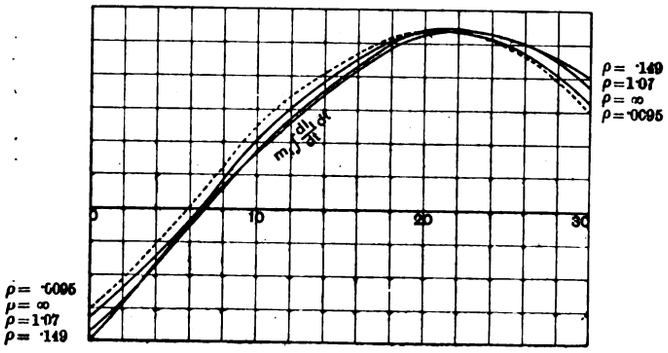

Fig. 8.

We now come to the armature. If the leakage is known, and we have examined it in this motor, it is not difficult to deduce the fe_1dt, fe_2dt and fe_3dt curves when $\rho=\infty$, since there is no disturbance due to armature currents. We have to investigate the relations between these curves for $\rho=\infty$, and when ρ has diminishing values given to it down to zero.

If the ordinary self-induction theory be assumed, and if the coils on the armature were simply closed on themselves and not pooled together as in this three-phase arrangement, the relation could be expressed in the form of the equationse: $_1$ (for $\rho=\infty$)$=(r_1+\rho_1)$ y_1+Li_1; e_2 (for $\rho=\infty$)$=(r_2+\rho_2)$ y_2+Li_2; e_3 (for $\rho=\infty$)$=(r_3+\rho_3)$

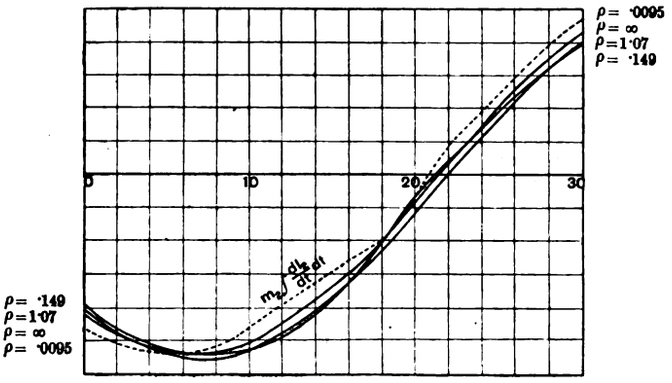

Fig. 9.

y_3+Ly_3; where L is a co-efficient of self-induction. Integrating the above from time 0 to time t and equating periodic parts, we have—

$$\int_0^t e_1\,(\text{for }\rho=\infty)\,dt=\int_0^t(r_1+\rho_1)\,y_1\,dt+\mathrm{L}y_{1t}$$
$$\int_0^t e_2\,(\text{for }\rho=\infty)\,dt=\int_0^t(r_2+\rho_2)\,y_2\,dt+\mathrm{L}y_{2t}$$
$$\int_0^t e_3\,(\text{for }\rho=\infty)\,dt=\int_0^t(r_3+\rho_3)\,y_3\,dt+\mathrm{L}y_{3t}$$

If the epochs be chosen when y_1 y_2 y_3 are zero, the last term in each equation vanishes.

In our case the electromotive force of an armature coil is not $(r+\rho)$ y at any moment owing to the influence of the respective coils on one another. The extent of this disturbance can be judged by an examination of the phase difference between e_1 and y_1, e_2 and y_2, and e_3 and y_3 in each case (*see* Tables IX. and XIV.). But by variation of L we may write—

e_1 (for $\rho=\infty$)$=e_1$ (for $\rho=a$)$+\mathrm{L}y_1$; e_1 (for $\rho=\infty=e_1$ (for $\rho=b$)$+\mathrm{L}y_1$ where $a\,b$ — — — are the values of ρ in the acual experiments. In these cases also when $y_1=0$ we have—

$$\int_0^t e_1\,(\text{for }\rho=\infty)\,dt=\int_0^t e_1\,(\text{for }\rho=a)\,dt$$
$$\int_0^t e_1\,(\text{for }\rho=\infty)\,dt=\int_0^t e_1\,(\text{for }\rho=b)\,dt$$

and so on for e_2 and e_3.

Now the curves e_1, e_2, e_3, for $\rho=\infty$, a, b, — — — obtained at frequencies 52 and 95 (see Tables V., VI., VII., VIII., X., XI., XII., XIII.), have been integrated, and the difference between the ordinates (when $y_1=0$) of fe_1 (for $\rho=\infty$) dt and fe_1 (for $\rho=a$, b — — —) dt, which on the theory should be zero, is *not* zero. It appears that as ρ is varied the fe_1 (for $\rho=\infty$) dt curve must be increased to cut the other when $y_1=0$, up to the value of ρ corresponding to maximum torque, but that after this with $\rho=0{\cdot}01$ ohm, the fe_1 (for $\rho=\infty$) dt curve has to be decreased to cut the other curve when $y=0$; and so for e_2, e_3. The extent to which the ordinates have to be altered is given in Table XV. for the frequencies 52 and 95.

If the ordinates of the curve fe_1 (for $\rho=\infty$) dt be increased or decreased according to the difference found in this way (when $y_1=0$), for the different positions of the phase, then the relation between such modified curve and fe_1 (for $\rho=a$, b — — —) dt is to be accounted for by the term L y_1 and so for e_2 and e_3. This has been done for different positions of a half period and the value of L deduced. The collected results are given in Table XVI. Fig. 10 gives one set of curves, and Table XVII. shows how L has been deduced. The values of L are not constant, but as ρ is decreased we see that L becomes somewhat smaller. This may be connected with the disturbances shown in Figs. 8 and 9. The maximum value of L is $1{\cdot}8\times10^{-6}$ C.G.S.

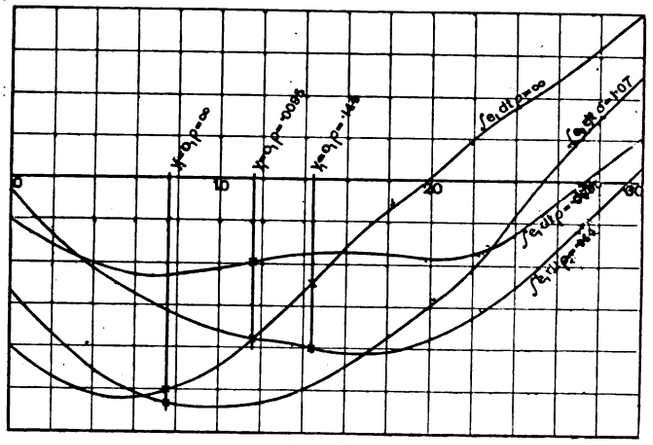

Fig. 10

units according to the experiments. We can calculate the value of L approximately from the magnetic circuit of this motor. The area enclosed by one armature coil is measured and found to be 280 sq. cm. The length of the air space can be taken to be 0·175cm. Then the induction due to unit current-turn (C.G.S.) is approximately 4π 280/0·175$=$20,110 C.G.S. units.

The reaction will be that due to the rate of change of this flux multiplied by 6 $(n/6)^2$, where $n/6$ is the number of turns per coil, there being six coils in series. In this armature $n=24$, so that $\mathrm{L}=6\times16\times20{,}110=1{\cdot}9\times10^6$ C.G.S. units as against $1{\cdot}8\times10^6$ found in the experiments.

This, then, gives an account of the armature reaction in this motor. Its effect is to increase and then decrease electromotive force as the external resistance ρ is varied as shown in the experiments.

An examination of the results in Tables IX. and XIV. shows that as ρ is decreased, the phase difference between e_1, e_2, e_3 (for $\rho=\infty$) and the currents y_1, y_2, y_3 increases up to the point of maximum torque; after this the effect at 52 periods per second is to slightly increase phase difference, but at 95 periods per second phase difference is decreased. The currents are not displaced a quarter period, in which case their demagnetising effect for a given current would be greatest. One has only to examine Tables VIII.* and XIII. to see how violent the reactions are when ρ has the smallest value. The torque fluctuates in any coil between positive and negative values; the effect is a differential one: on

* Paper read before the Institution of Electrical Engineers, March 9.

* The experiments in this Table were very difficult to perform owing to the rapid heating of the alternators—the load was so excessive. It will be seen that the instantaneous value of $y^1+y^2+y^3$ is not always zero. However, the deductions are amply borne out by Table XIII., which is well up to the average accuracy of these experiments.

Digitized by Google

the whole there is a small positive torque. If we consider $r+\rho$ the independent variable, and the torque the dependent variable we have for large values of $r+\rho$ the currents y practically in phase with impressed electromotive force e (for $\rho=\infty$): the torque is small because y is small. As $r+\rho$ decreases the angle of lag of y increases, it is true, but y also increases, and we have seen that the electromotive force e (for $\rho=\infty$) is also increased by armature reaction as distinct from self-induction pure and simple; the torque increases. This goes on until the torque has a maximum value. After this, on further reduction of $r+\rho$ until $\rho=0{\cdot}01$ ohm, although phase difference is not greatly altered (it may even be decreased) the current y is increased; armature reaction diminishes the electromotive force very greatly, with the result that the torque decreases.

During these experiments I have received help from Messrs. Greenbank, Davey, Renfree, and Poole, past and present student demonstrators in the Siemens Laboratory, King's College, London. To these gentlemen I tender my thanks. I wish specially to acknowledge the assistance I have received from Mr. Renfree in the working out of results.

"Electricity: the Universal Force." By H. R. Rogers. (Buffalo: City Press Printing House.)

ELECTRICITY WORKS ACCOUNTS.

Bradford Municipal Electric Supply Works.

Having started supply in September, 1889, the Bradford municipal electricity Supply undertaking has now completed its ninth year of working.

During 1898, the accounts for which are analysed in the first table, the loan capital has been increased by £42,600 borrowed, £40,000 at 3 per cent., and the balance at rates from 2⅞ per cent. to 2¾ per cent. Of the total amount of £167,312 borrowed, £6,525 has been repaid. The expended capital has increased by £28,353, and the total now stands at £170,225, representing £61·5 per kilowatt of plant available for generating purposes.

The business appears to be increasing at a very satisfactory rate judging from the increased output, which exceeded that of 1897 by as much as 42·9 per cent. The average price obtained per unit comes out at the very moderate figure of 3·6d., the total revenue from all sources being 3·75d. per unit. Notwithstanding the moderate tariff, however, the expenditure is no higher than 42·9 per cent. of the revenue, and at 1·61d. per unit for total costs, is something like 0·5d. *below* the average for municipal stations of similar output during 1897. This result is an excellent one, especially considering that, included in this figure for the total costs at Bradford there are charges which, though perhaps chargeable in the revenue account, appear somewhat unfairly therein to the extent they do. It will be noticed that in the item "Repairs, renewals of mains, &c." there is a sum of £669 to "Incandescent lamps for free supplies." Then there is under "Management" £698 to "bank interest and commission." These two sums together represent 0·23d. per unit, and this, deducted from the 1·61d., we have 1·38d. as the remaining total costs. The fuel costs, at 0·327d., is more than a ¼d. below the average of similar stations, and generating costs, at 0·794d., compare very favourably with 1·25d., the approximate average (for 1897) for stations with an output of 1,419,000 units in the year. These costs, in combination with the low expenditure on capital account, are results of which Bradford has every reason to be proud. No doubt the tramways, as a customer, contribute substantially to the economy effected, but it should be noted that the load factor is not above or up to the average.

Turning to the financial results, the working profit for the year was £12,678, representing 8·12 per cent. of the mean capital. Out of this was paid £3,249 to the depreciation fund, £4,730 to reserve, and £3,350 as interest on the loans. There is thus a balance which, with £9,425 from the previous year, amounts to £10,827.

Newcastle-upon-Tyne Electric Supply Co. (Limited).

The date of commencement of supply being in 1889 the undertaking of the Newcastle-upon-Tyne company has completed with 1898 its ninth year of working. Since the last accounts £6,854 of share capital has been paid up, raising the total received capital to £78,149. The total amount expended is about £98,183, or £75·5 per kilowatt of generating plant. With a 34 per cent. increase in the equivalent lamp connection the output has risen from 660,906 to 803,789 units sold, or about 22 per cent.

The average revenue from supply was 3·87d. per unit sold, or counting all sources 4·375d. Owing to the meagre information contained in the abstract of the accounts supplied us we are unable to separately render the items of expenditure either on capital account or out of revenue. It will be seen that the works costs show a sensible improvement over those of 1897, and that they are well below the average in company undertakings of equal annual output. The management and property charges have increased, but not by much, and the costs are still below the average of similar stations.

There is an item in the net revenue account which we have, following the original accounts, kept out of the works expenditure account. This item is one of £1,295 to "special expenditure on dynamo reconstruction, &c, during year." As will be seen we have included this £1,295 with the £1,000 paid to depreciation and reserve. The working profit for the year was £8,140, and this with a balance of £652 from 1897 has enabled an ordinary dividend of 8 per cent. to be paid after satisfying the interest charges.

Arrangements are in progress for increasing the capacity of the station and also for giving a continuous current supply for power and other purposes. To meet the expenditure thus entailed an issue of 8,000 new shares has been made.

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Aberdeen (Municipal)	1899	Jan. 6	Kensl'gton & Knightsbr' (Co.)	'99	Mar. 3

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON,

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co.'

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 6d.	16s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By R. Tennant Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particular on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. Vol. I. Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. NEW EDITION. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 93 original illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 3d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 3d., post free, 3½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O. J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 3s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

SPECIAL NOTICE.

NOW READY.—Vol. XLI. of "The Electrician," bound in strong cloth. Price 17s. 6d., post free 18s. 6d. Also ready, Cases for binding. Price 2s., by post 2s. 3d.

A complete set of the Second Series of "The Electrician" can now be supplied. These sets are very scarce, and early application should be made.

THE WEHNELT INTERRUPTER.

In days gone by, a new discovery or invention was frequently left almost unheeded by the scientific world until the inventor himself had developed it, and had, with the utmost pains, succeeded in convincing others of its value and importance. Nowadays, the mere publication of the result of an investigation or an experiment will sometimes suffice to awaken general interest, and will incite scientists, from those at the top of the tree down to the humblest students, to repeat the experiments and to extend them, seeking, if a new principle has been discovered, a wider bearing for it, analogies to it, and further elucidations of it; and, if it be a new invention, endeavouring to extend its utility and application. Whether these workers are impelled solely by the true spirit of philosophic inquiry, viz., by the desire to dive further into the secrets of nature, or whether their wish is the more worldly one of having their names associated in some way or another with what may be a great invention, it would be invidious to ask. It is enough that the motive is there, and may produce valuable results. Although the discovery by Dr. Wehnelt of the electrolytic interrupter cannot be compared in importance with, for instance, that of Röntgen rays or of the means of practically employing Hertzian waves for telegraphic purposes, it is eliciting almost as much experimental investigation as the former, and even more than the latter. The reason, evidently, is that Wehnelt's apparatus can be reproduced simply and cheaply, and that the results to be obtained from its two pieces of metal dipping in dilute sulphuric acid are almost as unexpected and startling as was the discovery of the amount of energy contained in one element of Volta's *couronne de tasses.*

The form of interrupter used by Wehnelt himself consisted of an anode of platinum and a cathode of lead, contained in a beaker of dilute sulphuric acid. It being essential that the exposed surface of the anode should be small, a platinum wire sealed into a glass tube and projecting a few millimetres into the acid was employed, the tube being filled up with mercury. This simple cell, placed, instead of the usual interrupter, in series with the primary of an induction coil, effectually broke the circuit automatically over a thousand times a second. Twelve volts sufficed to make the cell work as an interrupter, but to get these high frequencies of interruption a larger voltage was necessary, the frequency increasing with the

Digitized by Google

voltage. The apparatus has only been altered as to small matters of detail by subsequent experimenters. Most have found that the glass tube which surrounds the anode breaks off, owing either to the intense heat or to the mechanical force acting on it, and an ebonite tube or a tube with an ebonite stopper has been substituted. M. D'Arsonval, however, prefers to employ a test-tube in place of the beaker, and to bring the platinum wire through the glass at the bottom. The use of a copper wire soldered to the platinum, in place of the mercury connection, has also been preferred, and some have constructed multipolar interrupters, while Prof. Silvanus Thompson has found that the regularity of interruption is improved by causing a jet of air to flow rapidly past the anode. From the first, Wehnelt observed that inductance in the circuit, so far from being a disadvantage, actually helped the effect, and that a higher voltage was necessary if no inductance was added. This was confirmed by subsequent experimenters, and gave rise to the explanation that the phenomenon was essentially one of resonance. Prof. Thompson, in his letter published in our columns, was among the first to explain how this was so. The evolution of the gas on the small surface of the anode sufficed to cause the initial instability, and the capacity of the anode, together with the self-induction in the circuit, kept up an oscillatory current. M. Blondel has found, however, that investigation into the cause of the Wehnelt effect was one eminently suited to his oscillograph, and the result of his researches, which we publish in another column of this issue, appears to afford a good explanation of the recondite phenomenon. Some other remarkable observations remain to be elucidated, however. Mr. Campbell Swinton has found that the fatigue, which sets in after about a quarter of an hour's working, is not due to the heating of the electrolyte, as it is not eliminated by placing the cell in a water bath, and Dr. D. K. Morris has succeeded in temporarily removing the fatigue by merely reversing the current. Mr. Beattie has measured the frequency by observing with a dynamometer the condenser current flowing into a condenser shunted across the cell, and he finds that it does not correspond with the note emitted by the arc. Mr. Beattie necessarily assumed a simple periodic current, and the discrepancy is explained by an examination of M. Blondel's curve. Mr. Hill's observation that hydrogen as well as oxygen can be collected at the anode and his explanation of it may be also noted. Possibly this may imply a reversal of the current, but with equal probability, we think, it may be associated with the remarkable reversal of the ions of H and O observed by Prof. J. J. Thomson in the electrolysis of steam.

Coming now to the probable usefulness and applicability of Wehnelt's device. Prof. Lodge, at the Physical Society, dispelled the idea that the new interrupter would improve Hertzian wave telegraphy to any extent, but its effect on X-ray work appears invaluable. All workers testify to its decreasing the time of exposure required, and to its eliminating the troublesome flickering observed on the fluorescent screen. Then, as pointed out by Mr. Brooks in our last issue, and also by Prof. Elihu Thomson, it renders possible the use of alternating current mains for working the induction coil, with the same simplicity as when utilising the continuous current supply, and its importance in this respect to the medical profession is hard to over-estimate. In other directions also the Wehnelt interrupter is likely to prove of value. Alternating or rapidly-interrupted currents are frequently required for lecture demonstrations in buildings supplied only with continuous current. Prof. Elihu Thomson has also worked a welding transformer by its means, and he even describes how a Wehnelt electrolytic musical box may be constructed, which last may prove useful as a lecture room experiment, but will have, we sincerely hope, no direct practical utility. Prof. Fleming has found, at the expense of considerable repairs to his Tesla coil, that a Wehnelt interrupter in the primary circuit of the first induction coil greatly exalts the electromotive force at the secondary terminals of the Tesla coil.

In addition, therefore, to providing a pretty scientific toy, Wehnelt's discovery is destined to be of great value, both in aiding pure scientific investigation and as a useful adjunct in at least one of the most important recent applications of electrical science.

REVIEWS.

Electro-Dynamics. The Direct-Current Motor. By C. A. Carus-Wilson. (Longmans, Green and Co., London. 1898.)

Since his Paper on "The Design of Electric Railway Motors for Rapid Acceleration" was read before the Institution last year, the author's general method of treating electric motor problems is well known to electrical engineers. The work, the subject of this notice, may be characterised as a more complete discussion of the general subject of the continuous-current motor from the same standpoint as was taken up in the Paper referred to. A certain knowledge, by the student, of the use of the elements of design of motors is taken for granted, and the first chapter rapidly gets under way with a discussion and definition of the quantity christened by the author the "induction factor." The first and third chapters are thus taken up. Between them is sandwiched a chapter on "The Conditions of Uniform Motion," which is quite interestingly written, and contains on pages 24 and 25 a very clear discussion of the essential identity of the two kinds of communication of energy, viz., as heat and as work. Next, the peculiarities of shunt and series-wound motors are separately discussed in so far as they affect traction problems. Chapter VI., treating of "Efficiency," is a useful discussion of the subject, and deals clearly with the practical testing and with the analysis of the various losses in motors.

The "Force Factor" is another term for which the author is responsible. There seems more sanction for the introduction of this special term than for "Induction Factor" from the importance which the former quantity bears in relation to electric traction and the adequate rating of motors; this factor really stands for the quantity "watts per revolution per second." The author takes the view that this latter expression, as also "volts per revolution per second"—the equivalent of what he calls the "Induction Factor"—is misleading or inappropriate, as involving the idea of motion, whereas in his treatment of the subject the static conditions of the traction motor is of almost primary importance. There is a valuable chapter dealing with the subject of motor control; the examples and quantities used to illustrate the discussion in this chapter, and, indeed, throughout the book, are so often taken from actual practice, or the results of actual tests, that the various data and curves have an intrinsic interest and value apart from their primary function.

We are surprised to note that the word "tension" is exclusively used to denote what we usually term pressure, and that resistance or "C. R." drop is referred to as "heat drop." We congratulate the author on the general lucidity and the freedom from errors or misprints, and not least on the instructive data which he has included in the book. While, probably, practised engineers will prefer to interpret the expressions and symbols into forms they are more accustomed to before using them; nevertheless, the work should prove very useful on this special subject, and an excellent course to the student.

Canalisations Electriques. Lignes Aériennes Industrielles. By R. V. Picou. (Paris: Gauthier-Villars and Masson and Cie.)

In the present state of the electrical industry there is room for technical books with a narrow scope, dealing more fully with some special point in connection with electrical engineering than a treatise of more general character can do. An

Digitized by Google

excellent example of this specialised literature is the small volume before us, which forms one of an "Encyclopédie Scientifique Aide-Mémoire," published under the direction of M. Léauté. As the sub-title implies, the book is not devoted to electrical networks generally, but only to overhead lines; and for some reason, which we fail to understand, the word "industrielles" seems to confine the author to electric light and power lines, and to exclude telegraph and telephone conductors. The subject treated is still further narrowed by the omission of any reference to that special branch of line construction employed on tramways. Even with this limited range, however, this book should prove most useful, as it instructs the reader thoroughly in the mechanical design of a pole-line, and contains practical hints as to the choice of the material and its erection. There are, of course, some points in the book which are open to criticism, and others which may not coincide with the views and practice (limited, we allow) in this country. Among the former we may mention the unscientific mode of expression, applied to a lightning conductor, "C'est sa self-induction seule qui s'oppose à l'écoulement du fluide"; and among the latter, a paragraph on the needlessness of soldered joints in most cases.

Specification. No. 3. February—May, 1899. (London: The Proprietor of "The Builders' Journal and Architectural Record."

This publication, hitherto a quarterly, is now, commencing with the present number, to be issued half-yearly, the publishers finding that the immense amount of labour involved in the production of a work of over 600 pages renders it quite impossible to continue on the original plan. An additional number of interesting and useful articles appear in this issue. One of these, entitled "A Country House Electric Light Installation," by K. S. MacKinlay, is thoroughly good for its length, being well and concisely written. The section, entitled "Electrician," has been enlarged from about eight pages to about twenty-one. The new matter is chiefly the Board of Trade, Fire Office, the London Building Act and other regulations relating to electric lighting.

Of less direct interest to electrical engineers is a technical description with sections of the Leyton pressed sludge and dust destructor, by William Dawson, M I.C.E., the engineer and surveyor to the Leyton District Council. There are also some valuable hints anent pile-driving in the form of a report by the committee of the American Association of Railway Superintendents of Bridges and Buildings. Although the matter contained in this number is probably double that in the preceding number, the bulk of the book has been kept within limits by utilizing the blank pages hitherto left for notes. There is no doubt that the work as it is will prove a valuable acquisition to engineers, architects and surveyors.

INDUCTION MOTOR DIAGRAMS.

BY C. C. HAWKINS, M.A.

(*Concluded from page 612.*)

If the above results be now examined from the basis of a single resultant field actually existing, it is seen that not only is the maximum field passing through the armature reduced below that which would be due to the primary current alone, *i.e.*, is reduced to the value corresponding to e, but that it is again reduced to the value corresponding with $e \cos \phi_a$, and its phase is shifted backwards, so that the lines enter the armature with a lag ϕ_a behind the normal to the wattless magnetising current be, and with a still greater lag behind the normal to the total primary current. So long as there is an induced E.M.F. in the armature there are no actual lines produced by the armature current across the air-space in the resultant field, but the effect of leakage may be conveniently considered on the basis of two superposed fields, as if the armature current actually produced lines in the air-space and so had self-induction. Really the lag of entry continues to approach 90deg. until standstill of the motor occurs, and the resultant field through the armature becomes weaker and weaker as it becomes more and more distorted. The field wires do, however, actually have self-induction, the E.M.F. thereby produced being at right angles to the *total** field-current and increasing simply in proportion to it.

In Figs. 22-27 are drawn a number of diagrams for the same motor as in Part I., in which $R_f = 0{\cdot}75$, and $R_a a^2 = 0{\cdot}5$, the number of phases of the field and armature circuits and their numbers of turns being taken into account by the ratio of transformation a, so that whatever back E.M.F. is produced in the field, the induced E.M.F. in the armature is reckoned on the same basis. The variable that must be fixed for each diagram is the speed of the armature or which amounts to the same, the slip which determines the frequency f_1 of the armature currents.

With no current in the secondary, a magnetising current of 26·3 amperes produced such a field that the total back E.M.F. due to it is 100 volts. Out of the total number of lines, it has been assumed that 15 per cent. leak through the air without entering the armature, so that the self-induced E.M.F. in the primary is to the useful back E.M.F., as 15:85. Thus, for each ampere of magnetising current, we have a useful back E.M.F. of $\frac{85}{26{\cdot}3}$ volts $= 3{\cdot}23$ volts; and for each ampere of total current (any eddy-current component excepted) we have a self-induced E.M.F. of $\frac{15}{26{\cdot}3} = 0{\cdot}57$ volts.

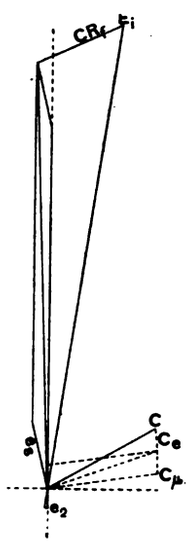

FIG. 22.—No load. 968 revs.
$x = 8°$. $\phi = 51{\cdot}6°$. $a = 8{\cdot}5°$.

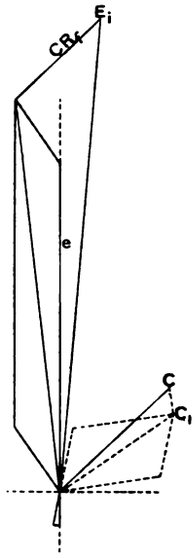

FIG. 23.—900 revs.
$x = 6{\cdot}25°$. $\phi = 41{\cdot}8°$. $a = 5°$.

The impressed E.M.F. is to be 100 volts, while the speed of synchronism is 1,000 revolutions per minute. Let the motor be 6-pole, so that the frequency of the field is $f = \frac{pN}{60}$ $= \frac{3 \times 1{,}000}{60} = 50$ cycles per second. Since the self-induced E.M.F. with no current in the secondary is 15 volts, and is $= 2\pi f C_\mu L$, the inductance of the field is $L = \frac{15}{2\pi \times 50 \times 26{\cdot}3} =$ ·00182. The inductance of the armature, L_a, reduced to the primary system, must with drum-winding be practically the same as that of the field, and we assume it therefore to be the same, viz., $L_a a^2 =$ ·00182. Take any speed of the armature, say 800 revolutions, then the slip is $\frac{200}{1000} = 0{\cdot}2$, and the frequency of the currents in the armature is $f_1 = sf = 0{\cdot}2 \times 50 = 10$. If ϕ_a be the angle of lag in the armature, $\tan \phi_a = \frac{2\pi f_1 L_a}{R_a}$, and in the present case with both L_a and R_a reduced to the primary system, $\tan \phi_a = \frac{2\pi \times 10 \times {\cdot}00182}{{\cdot}5} = {\cdot}228$ whence $\phi_a = 12{\cdot}85$deg. Take any value of the useful back E.M.F. in the field, say 85 volts, then the induced E.M.F. in the armature will be $85 \times s = 85 \times {\cdot}2 = 17$ volts, and the ohmic E.M.F.

* *See* preceding note.

Digitized by Google

will be $17 \times \cos 12{\cdot}85\text{deg.} = 17 \times {\cdot}975 = 16{\cdot}58$, whence $C_p = \frac{16{\cdot}58}{{\cdot}5} = 33{\cdot}16$ amperes. Draw a line OC_a at 12·85deg. to the vertical line Oe_3 (Fig. 24) and upon them mark off the values of the ohmic and induced E.M.F. Prolonging OC_a through O to C_p, the power component of the primary required to balance the secondary current must lie along OC_p and have a length = 33·16. Hence, along a line inclined to the vertical at an angle of 12·85deg., plot $C_p = 33{\cdot}16$, and along a line inclined to the horizontal at the angle of hysteretic advance $\beta' = 8{\cdot}5$deg., plot the magnetising current $C_\mu = 26{\cdot}3$, which is required to give the useful back E.M.F. of 85 volts. Compound the two, and the resultant OC_1 of 49 amperes is obtained. This current acting round the leakage circuit will produce a self-induced E.M.F. $= 15 \times \frac{49}{26{\cdot}3} = 28$ volts. No eddy-current component has as yet been introduced since any such component is directly balanced by the actual eddy-currents and does not magnetise the field. The current of 49 amperes which magnetises the leakage paths must itself be ahead of the leakage magnetism by a certain angle x owing to the hysteresis;

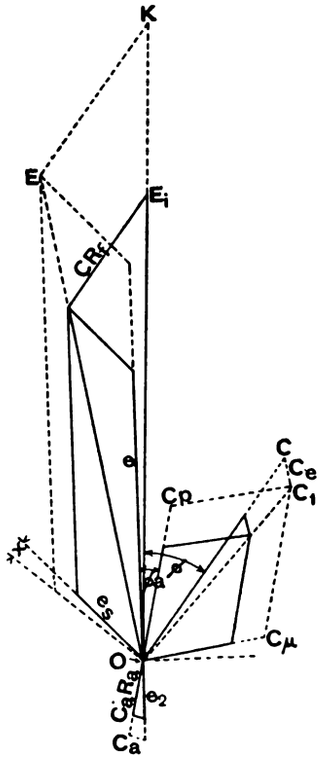

FIG. 24.—800 revs. Maximum efficiency. $x = 5°$. $\phi = 35{\cdot}2°$. $\alpha = 2{\cdot}5°$.

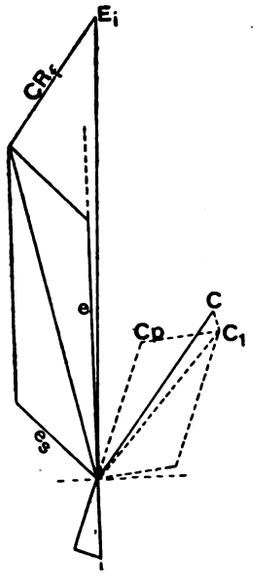

FIG. 25.—700 revs. Maximum H.P. $x = 4{\cdot}5°$. $\phi = 34°$. $\alpha = 2°$.

hence the self-induced E.M.F. is less than 90deg. ahead of the current by the same angle x. This angle by which it falls behind 90deg. cannot, however, be determined until the total back E.M.F., to the square of which the hysteresis watts are proportional, is known. An approximation must, therefore, at first be made by assuming some angle of lag for the total magnetism, less than 8·5deg. Since the inclination of the current OC_1 to the vertical is 43deg., the maximum angle between e_s and e would be 90deg. − 43deg. = 47deg., if there were no hysteresis loss due to the leakage lines; the resultant of e and e_s would then be $\sqrt{85^2 + 28^2 + 2 \times 85 \times 28 \cos 47\text{deg.}} = 106$. The actual angle between e_s and e must be something less than 47deg., and the total back E.M.F. will be rather more than 106 since e and e_s are more nearly in phase. If the total back E.M.F. be 107·5, the total hysteresis watts will be $388 \times \left(\frac{107{\cdot}5}{100}\right)^2 = 448$. Out of this we have already accounted for $85 \times 26{\cdot}8 \sin 8{\cdot}5°$ or $388 \times \frac{85}{100} = 330$, hence the difference still to be accounted for is $448 - 330 = 118$. This must be equal to the product of the self-induced E.M.F. and the projection of the current OC_1 upon it, *i.e.*, $28 \times 49 \cos(90\text{deg.} - x) = 118$, whence $\cos(90\text{deg.} - x) = \frac{118}{28 \times 49} = 0{\cdot}086$, and 90deg. $- x =$ nearly 85deg. Hence plot e_s 85deg. ahead of the current, and compound with e, whence we obtain the resultant total back E.M.F. OE = 107·5 volts.

The eddy-current loss like the hysteresis loss is proportional to the square of the total back E.M.F.; it will, therefore, be $562 \times \left(\frac{107{\cdot}5}{100}\right)^2 = 650$ watts. The eddy-current component must be in phase with the total back E.M.F., and will be $= \frac{650}{107{\cdot}5} = 6{\cdot}05$. From the extremity of OC_1 a line $Ce = 6{\cdot}05$ (Fig. 24) must, therefore, be drawn parallel to OE the total back E.M.F., and this must be compounded with the previous component of 49 amperes. Thus the resultant total primary current OC is found to be 53 amperes. The loss of volts over the primary resistance is then $53 \times 0{\cdot}75 = 39{\cdot}8$ volts. From the extremity of the total back E.M.F. OE draw a line EK parallel to OC, and along it plot the loss of volts = 39·8. Join OK, then OK is the E.M.F. that must be impressed in order to give the back E.M.F. of 85 volts, &c. It scales, however, 137, so that the whole diagram must be reduced in the proportion of

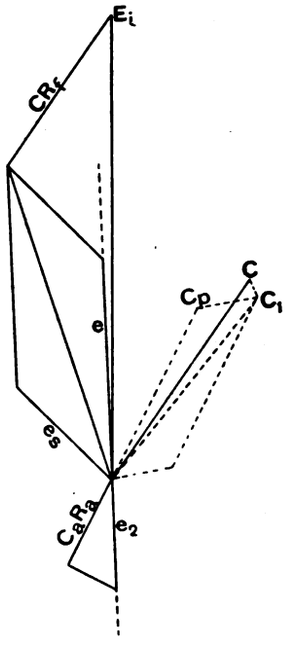

FIG. 26.—500 revs. Maximum torque. $x = 4{\cdot}25°$. $\phi = 35{\cdot}9°$. $\alpha = 2{\cdot}5°$.

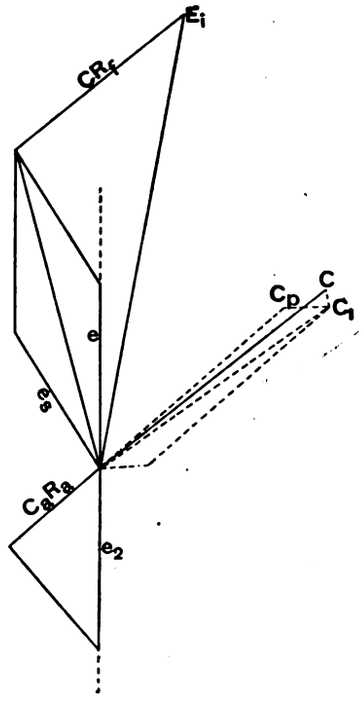

FIG. 27.—Standstill. $x = 3{\cdot}75°$. $\phi = 40{\cdot}6°$. $\alpha = 10{\cdot}5°$.

100 : 137, as shown by the similar triangles marked in heavier black lines. To begin with the secondary, the induced E.M.F. will be 12·4 instead of 17, and the ohmic E.M.F. will be 12·1 instead of 16·58. The magnetising current C_μ and the power component are reduced to 19·2 and 24·2 amperes respectively, and the total current to 38·7. The useful back E.M.F. is now 62 volts instead of 85, and the self-induced E.M.F. corresponding to 38·7 amperes of total current, or 36 amperes without the eddy component, is 20·5.

The advantage of plotting the various quantities as in Fig. 24, so that the current lines fall to the right of the diagram and the E.M.F. lines to the left, is that the projection of the current lines on the volt lines gives the various items of work involved. Thus, the projection of OC_1 on e gives the work done in the armature, including a share of the hysteresis loss in the field due to the useful lines. The projection of OC_1 on e_s gives the remainder of the hysteresis loss: if e_s were at right angles to OC_1, there would be no work therein involved, the total back E.M.F. and the projection of OC_1 on the line of total back E.M.F. being inversely altered. But now the projection of OC_1 on the total back E.M.F., gives

the work done in the armature plus all the hysteresis loss in the field due to both useful and leakage lines, and the projection of C on the total back E.M.F. gives all the work done

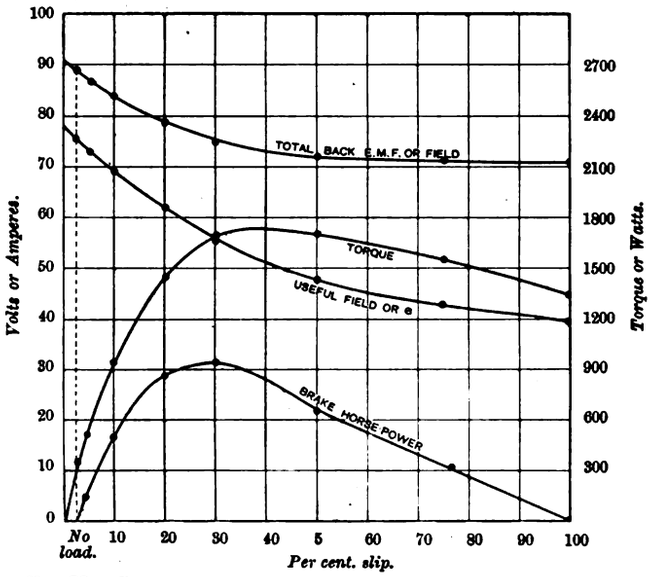

Fig. 28.—Current, torque and H.P. per phase, with magnetic leakage.

(including the eddy-current loss) other than heating the primary winding. Finally the projection of C on E_i gives the total energy consumed in all ways.

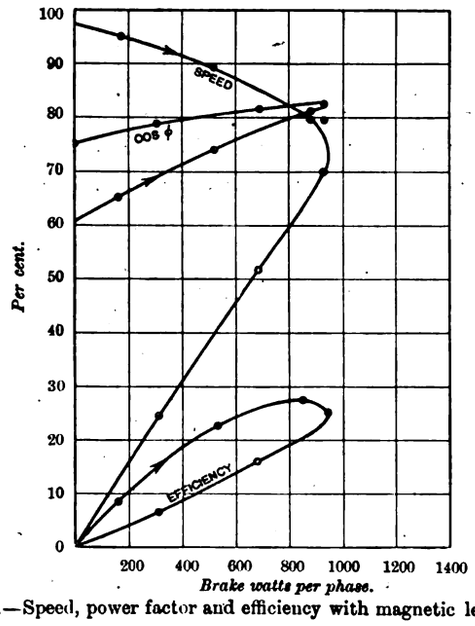

Fig. 29.—Speed, power factor and efficiency with magnetic leakage.

For loads within the working range of the motor, e_s is small, and little error is involved in plotting C_0, as was previously done in part 1 when magnetic leakage was absent, but for overloads when the angle of lag of the secondary current is large, the more precise method above described is necessary. It will be seen that for small loads C_e is virtually a prolongation of $g_h e$, the power component of the magnetising current, but as the angle of armature lag increases, the inclination of C_e to $g_h e$ increases. Further, the eddy component does not decrease so fast as the magnetising current, since the total field does not decrease nearly so fast as the useful field (*cp.*, Fig. 28). In fact, from no-load to standstill the eddy component only decreases from 5 to 3·97, and there is appreciable error in regarding the eddy component as in phase with e rather than in phase with the resultant of e and e_s.

From a number of such diagrams for various speeds, all the characteristics of a given induction motor can be derived (Table II.) and plotted as before (Figs. 28 and 29). It will be found that ϕ is large at no-load, and gradually decreases up to a certain point, when owing to the leakage and self-induction of the primary, it agains begins to increase. Hence,

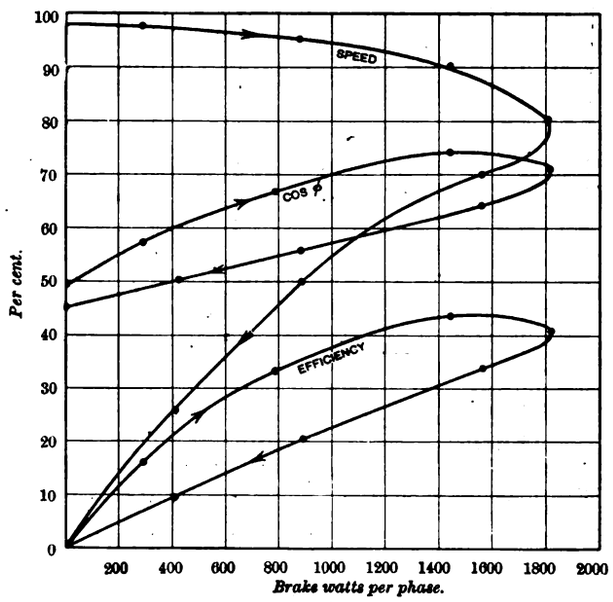

Fig. 30.—Speed, power factor with magnetic leakage, and with $R_a\, a^2 = Rf = \cdot 25$.

at a certain load, there is a maximum value of the load-factor cos ϕ, although this does not necessarily coincide with the point of maximum efficiency. At no-load there is but a small angle between E_i and e, but as the speed decreases E_i advances up to or beyond e and attains a maximum point of advance, after which it again recedes. The total watts transmitted to the armature per phase $= e\, C_p \cos \phi_a$, and the torque per phase, which is proportional to the former, reach their maxima at the same time, and this is for the load and speed when the impressed E.M.F. is furthest ahead of e, or if it is never ahead of e, is least behind e; *e.g.*, in our case when $a = 2°$ or E_i is only 2° behind e. A comparison of Figs. 28 and 29 with Figs. 17 and 18 shows the immense effect of leakage in reducing the power-factor, torque, efficiency, and brake watts of the motor; it further alters the relative position of their maxima.

Digitized by Google

It has been shown that cos ϕ, instead of increasing continuously (as it does when magnetic leakage is absent), reaches a maximum and then declines. With the data of our imaginary motor, however, its value at standstill is still above its value at no-load, yet in practical motors this is not the case, but the curve of cos ϕ relatively to brake horse power curves round and descends below its ascending values. The reason for this is to be found in the lower values of resistance and consequent greater armature lag in the practical case of an efficient motor. Thus, if the resistances of armature and field-winding be reduced to 0·25 each, and all else is left unaltered, we obtain the curves of Fig. 30, corresponding to those of Fig. 29. This single instance serves to show how much information can be gained from induction motor diagrams as to the relative effect of altering one at a time the values of the data.

THE MILAN-MONZA ELECTRIC RAILWAY.

The problem of substituting electric traction for steam on the railways in Italy has been actively discussed during last year by the Italian Government and the leading Italian railway companies. It is now contemplated by the latter to carry out practical experiments on several trunk lines of secondary importance, in order to ascertain the value of the various systems proposed. The first application has been made on the Milan-Monza line, which is a line common to the Mediterranean and the Adriatic Companies. Accumulator traction has been substituted for steam, and the inauguration of the new system took place a few weeks ago. We give herewith a brief description of the plant, which is now in regular operation.

The power house is situated in the central railway station at Milan. The supply current is three-phase, at 3,600 volts pressure and 42 periods, and is derived from the network of the Edison Company. It actuates a Schuckert motor generator, consisting of a three-phase induction motor of 100 H.P. and 400 revolutions, directly coupled to a continuous-current dynamo of 67 kilowatts at 250 to 350 volts. From the switchboard the continuous current is led to the car house (70 metres distant) for charging the batteries.

The line is about eight miles long, and is entirely operated by motor cars, each containing a battery of 130 traction cells and a small battery for lighting. The cars have been supplied by Messrs. Grondona, Comi and Co., of Milan, and are of the double-truck type, with two covered platforms at the ends; their dimensions are: 60ft. long over all, 9ft. 6in. wide, and 8ft. 4in. high. The body of the car is divided into two first-class and two second-class compartments, and contains 64 seats and standing-room for 26 passengers. The compartments are inter-communicating, entrance being made by the end platforms. At the extremity of each platform is a cab for the motorman.

The motor equipment consists of two 50 H.P. single-reduction motors, series-wound and four-polar, the reduction being in the ratio of about 1 to 8; the suspension is of the usual type, but with a double spring at each end. Each truck has a motor operating one of the axles, while the other axle is idle. There are two controllers on each car, and each consists of two independent commutating cylinders—one for connecting the circuits, and the other for inserting resistances.

Two sets of 65 Hensenberger cells form the battery. These are usually connected in series, giving an average discharge pressure of 235 to 275 volts. With accumulators fully charged, a length of 31 miles may be run at the regular speed of 29 miles per hour. The accumulators are placed in boxes under the floor of the car, and the possibility of gases penetrating to the interior of the car is fully avoided. In addition, while the car is in the motor-house for charging, an electric pump is employed for extracting the gases from the interior of the boxes.

Braking the car is effected by a hand-brake and a Westinghouse air-brake; the latter is supplied by an electric compressor, which supplies also the acoustic signals. The cars are completely lighted by electric lamps. There is a 10 c.p. lamp in each single room, a 16 c.p. lamp on each platform, and a 16 c.p. lamp in the motorman's cab. Externally the car has five lamps of 25 c.p., coloured according to the usual rules of the Italian railways. The lighting current is supplied by a small battery, placed near the principal one.

The motor-car, without passengers, weighs 58 tons in all, of which 16 represent the weight of the accumulators. This corresponds to about 1,800lb. per seat. A regular speed of 29 miles per hour is maintained in service, but in the tests the cars have reached a speed of 38 miles without difficulty. The whole electrical equipment of the power-house and the motor-cars has been supplied by Messrs. Schuckert and Co., of Nuremberg.

THE HISSING OF THE ELECTRIC ARC.

The following is an abstract of the first day's discussion in connection with Mrs. Ayrton's Paper at the Institution of Electrical Engineers on Thursday, March 23rd:—

The PRESIDENT (Mr. J. W. Swan), after complimenting Mrs. Ayrton on her Paper, which formed, he thought, quite a model of scientific method in research, said that he felt much astonished at the great progress that had been made, and the perfection that had been realised in the arc method of electric lighting. He remembered how the very first arc lights spluttered and hissed; and the trouble in connection with these was not entirely, as Mrs. Ayrton had pointed out, due to defects in the lamps themselves, but due in a very considerable measure to defects in the carbons. Carbons at that time were cut square or octagonal, and were made out of some hard substance such as was now found in gas retorts. Considering the many circumstances which tended to its instability, arc lighting had reached a wonderful point of perfection; he should have thought it was almost finality, had not Mrs. Ayrton shown that it was possible to advance still further. Amongst other practical applications of this discovery—for he could speak of the work of Mrs. Ayrton in no other terms than as a discovery—he thought they would no longer use the fluted carbons that had been used in connection with lighthouse illumination.

Prof. SILVANUS P. THOMPSON said that they now had a practically new definition of the term "hissing arc." Apparently there were several things that a hissing arc did. It made a noise, it showed a greenish colour (this was also a discovery of Mrs. Ayrton's); it spurted; it produced mushrooms; it covered the surface of the crater for the time being with a kind of cloud or nebula, and it was accompanied with a very distinct drop of potential. But which of these things was to be taken as the criterion? He had always thought the noise should be taken as the criterion, and he was not altogether sure that it was not still to be taken. But yet, after all, the drop in potential appeared to be most important in Mrs. Ayrton's mind, because she had pointed out again and again how in some cases the potential dropped and in others it did not. They had seen put upon the screen two arcs side by side, one of which was open and the other enclosed. When the current was increased through both of them, and they heard a hissing noise, they were told that it was the open arc that was hissing and not the enclosed, while to all appearances it was the enclosed, because it had spurted all over the place. It was very difficult how to tell what was a hissing arc and what was not, and he hoped Mrs. Ayrton, in her reply, would make it quite clear. There had been a remark made early in the Paper, referring to the discussions at different times upon the physics of the arc. They had been told to look in diagram 1 at the last line comparing the 1 mm. arc, and Mrs. Ayrton had pointed out that if they had the arc in the silent state they might increase the current up to 14 amperes and no more; after that they might have a hissing arc with 17 amperes, but that they could not possibly have an arc either silent or hissing at 15 amperes. Now this fallacy—for fallacy it certainly was—had been supported by Professor Ayrton, but Mrs. Ayrton herself now supplied the antidote. They used to be told that if they had an arc, and kept the potential difference constant, and then lengthened the arc, the current increased instead of decreasing; but he ventured to point out that it was a fallacy. What they did was to lengthen the arc, and at the same time they did something to the external circuit to prevent the potential falling, and what they did was to increase the current in order to keep the potential up, and the result was that they had a larger current for a longer arc. He thought Mrs. Ayrton rather underrated Mr. Trotter's work; Mr. Trotter had obtained very similar results to Mrs. Ayrton some years ago, although he (the speaker) did not know that they had been mentioned in any Paper on the subject. He had intended to refer to the question of the shapes of carbon, but Mrs. Ayrton's researches had proved that square carbons were to be deprecated. It was now definitely proved that the hissing of the crater was intimately connected with the access of oxygen complicating the effects at the crater surface, yet there was a great deal behind that to explain why that complication should of itself set up the instability and the drop of potential.

Mr. W. M. MORDEY said that Mrs. Ayrton had not made quite clear to him whether instability was always an accompaniment of hissing, or not. If it was not, then they need not mind having an arc that did hiss. He mentioned this because of the reference to fluted carbons in lighthouse illumination. He had only been in a lighthouse once when the lights were on, and the arc was hissing the whole of the time. But it was, nevertheless, a good, steady, useful light, and they must remember that these fluted carbons added to the useful effect of the arc by allowing the light to get out. One of the drawbacks of arc lighting was that the light was given off from the surface of the crater, and only to a very small extent usefully

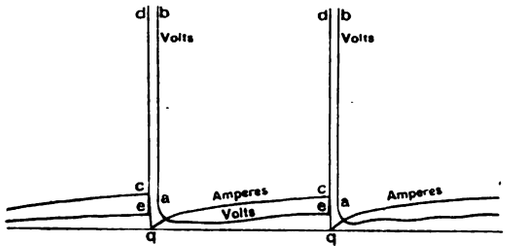
Digitized by Google

directed its rays to the objects that had to be illuminated. It was on that account that Sir James Douglas (a former member of the Institution) introduced, when he was the engineer to Trinity House, that form of fluted carbon which he believed was always used in the lighthouses round our coasts. However, he thought there was still a large field to be explored in connection with fluted carbons and alternate current arcs, and he hoped Mrs. Ayrton would give them a Paper on the physics of the alternate current arc generally, as well as on the hissing. He would like to mention a point in connection with alternate current arcs that had attracted his attention, which, perhaps, Mrs. Ayrton might be able to explain at the end of the discussion. There was seen, with alternate current arcs, a dark band halfway between the carbons reflected on the globe. It was seen on an ordinary 14in. globe as a dark band of about 1½in. or 2in. wide. With a low period alternate current, say 50 per second, there was a regular steady pulsation that was not connected, so far as he could see, with the periodicity. The periodicity was far too high to be noticed with the eye, but if this band was watched it would be seen to increase and decrease in breadth—perhaps 25 per cent. or 30 per cent. of its total breadth—at a rate of 400 or 500 times a minute. As there were with a 50 period current 6,000 currents a minute, there could be no connection whatever between this slow and regular beat and the periodicity itself. He had tried by various experiments to ascertain the cause of it, but without success. It was nothing to do with the mechanism, because it happened when the carbons were clamped perfectly steady. His last point was would Mrs. Ayrton explain the cause, if it were known, of the more granular appearance of the luminous surface of the carbons in the enclosed arc.

THE WEHNELT ELECTROLYTIC INTERRUPTER.*

BY A. BLONDEL.

The action of the curious Wehnelt interrupter, recently presented to the Académie by M. D'Arsonval, has not yet been fully explained. It has been well established by experience that the essential condition for its oscillatory working is that the circuit be inductive.† Without self-induction, the interrupter immediately stops working, the anode gets red, and a very weak current passes



continuously. The self-induction of the coil, or a supplementary inductive coil suffices to produce the phenomenon, and the frequency of the latter may be varied from one to several thousands per second by varying the inductance. One may, therefore, think, with the numerous writers who have already expressed their opinion, that it is a question of resonance between the self-induction and the capacity of the condenser formed by the polarised anode. This capacity may, for instance, reach one or two microfarads with a platinum wire 10mm. long and 0·5mm. diameter.

But this interpretation, based on the hypothesis of sinusoidal variations for alternating currents, would not explain how the increase of electromotive force, working on a circuit of invariable composition, can increase the frequency. Neither does it seem to be confirmed by a direct study of the current curve. For example, the curve in the figure, copied from curves of current and electromotive force taken by means of my 5,000 period oscillograph, by MM. Duris, Farmer, and Tchernosbitoff under my direction, indicates a single oscillation. The experiment was made at 40 periods, with a self-induction of from 0·2 to 0·3 henry in series with the interrupter. The latter had a wire similar to that already referred to. The pressure of the battery was 33 volts, the current 5 to 6 amperes; the pressure at the terminals of the cell increased to 75 volts. The figure shows that the current is first established as in all inductive circuits; the electrolysis continues to increase until the production of the gaseous envelope around the anode, then directly it is completed there is a sudden interruption of the current, and, at the same time, an enormous increase in voltage, projecting the spot outside the field of vision. Then both the current and the pressure resume their initial values and the action begins again. The precaution which we have taken, to give to the circuit a slower proper period than that of the oscillograph, permits us to think that these indications may be relied upon.

* From the *Comptes Rendus*, April 4, 1899.

† This necessity has also been indicated by Dr. Fleming, M. Pellat and others.

Under these conditions the phenomenon of interruption only occasions one single aperiodic impulse. The energy $\frac{1}{2}LI^2$ accumulated in the self-induction, and liberated by the interruption of the current, causes the condenser formed by the polarised anode in the electrolyte to be charged at high potential. This condenser destroys itself by discharging in an arc which is formed between the platinum and the electrolyte, and drives away the dissociated oxygen. The anode is therefore immediately freed from gas, and is again in contact with the liquid which condenses the vapour, if any remains, and permits the current to flow again immediately. This action may be approximately compared with that of a hydraulic ram or a pulsometer. This explanation allows one to understand the necessity of a certain proportion between the self-induction and the anode without it being necessary to liken the phenomenon to a true resonance. One understands also why the employment of a high voltage, which increases the rapidity of the electrolysis, can increase the frequency. Finally, the form of the volts curve suffices to explain the large increase of the mean pressure at the terminals of the cell, pointed out by MM. Wehnelt and Pellat. The oscillograph used did not lend itself to an examination of the action at high frequencies, but one may fairly believe that the phenomenon preserves the same character whatever the frequency. The explanation which I have proposed may, therefore, be general.

ADDITIONAL OBSERVATIONS WITH THE WEHNELT INTERRUPTER.*

BY ELIHU THOMSON.

Alternating-Current Circuits.—The interrupter will even work on alternating currents, provided the period natural to the interrupter is high enough to allow the current to rise to the critical value during the half wave or during one alternation. By placing the interrupter in series with the primary of an induction coil and connecting them across the alternating circuit, a torrent of sparks appeared between the secondary terminals at full separation. This was replaced by the noisy arc when the terminals were closer together. Furthermore, the sparks, when obtained, appeared to be undirectional, another good point in favour of the interrupter when used with alternating currents. Hence there is no obstacle to the use of alternating current in working an induction coil without condensers in exciting Crookes' tubes by the discharges. This fact renders unnecessary the high-frequency apparatus and double-focus tubes commonly used with alternating currents, and reduces the apparatus to a simple induction coil and interrupter. It will probably be best to use a piece of platinum foil as a cathode in place of a lead plate, as this will add to the permanency where the current reverses, as in alternating-current excitation.

Interrupter in Parallel.—It is found that two, three, or four of the platinum-point anodes may be worked in parallel in the same acid bath, and that their limiting currents need not be equal, while the sharpness of interruption, even in this case, is not apparently impaired. Several interrupters worked in parallel act as a unit, and take up a rate due to the total current, or, at least approximately, to the sum of the single currents of the interrupters. The musical scale may be sounded by varying the grouping of various sizes of platinum-point anodes properly adjusted.

Inductances.—Interrupters may be made to work with a fraction of an ampere at low or high rates, depending on the inductance in circuit and the voltage. The inductance of the whole circuit, including the dynamo, is to be taken, unless a battery, a condenser or a dead-resistance load is across the terminals in addition to the branch containing the interrupter. The presence of the battery in shunt, or of the condenser, if large enough, or of the dead-resistance load, if sufficient, may practically annul the effect of the inductance of the dynamo circuit, leaving the inductance coil in series with the interrupter to alone control the rate of interruption with any given surface of platinum anode. In one instance two incandescent lamps connected across the mains near the interrupter brightened considerably when the interrupter was working. The rate of interruption was high, and was reflected into the supply leads as a high periodicity superposed on the continuous current.

Different Rates Simultaneously Produced.—Two or more interrupters, working at different rates, may be supplied from the same source. Part of the inductance in circuit may be common to the interrupters, and part be in branches through each interrupter, as before suggested.

Variation of Inductances.—Several ways of controlling the rate of interruptions may be employed. The writer has used an inductance coil with a switch for varying the turns of wire in circuit, and this has been placed in circuit with the primary of an induction coil and its interrupters. In one instance, a small transformer was made with an iron wire bundle for a core, 8in. long and three-

* Abstract from the *Electrical World* of New York.

Digitized by Google

fourths of an inch in diameter. Wound on a bobbin surrounding this core was a coil about 3½in. long, consisting of eight layers of No. 22 wire. This was the primary put in circuit with the interrupter. Outside the primary turns was a single layer of No. 12, 45 turns in all, or about 20ft. of wire. By closing the coarse secondary through a resistance which could be varied, the pitch of interruptions could be controlled, and, if desired, the musical scale sounded. Again, the wire core could be pushed in or drawn from the axis of the coil with the same effect, making this a sort of electrical trombone. Further, numerous taps were taken from the secondary layer, and these enabled more or less of the secondary to be closed, or partly closed through resistances or inductances to secure different rates or pitches. Similarly, in another case the taps were taken from the primary coil, no secondary being used, and the active length varied, which varied the rate. The sounds so produced are not very musical, but are definite enough in pitch to enable a tune to be played, and the device could doubtless be automatically operated by contact made through perforations in a moving paper roll.

Electric Welding.—A small-sized, open-core welding transformer was operated with entire success, and the same arrangement enlarged and otherwise adapted to the purpose can doubtless be employed on a much larger scale in commercial work. This would enable welding work to be done wherever the direct-current service is to be had.

New Method of Working.—The writer has tried with success the following method of working an induction coil: A Wehnelt interrupter was put in circuit with an inductance across a 110-volt circuit, direct current. In shunt to the interrupter only, the primary of the induction coil was connected through a condenser.

Repulsion and Rotation Experiments.—The new interrupter also furnishes a means whereby actions hitherto regarded as requiring alternating currents for their satisfactory demonstration may be produced from direct currents or circuits. The now familiar phenomena of repulsion of rings, plates, or the like, rotations of discs, &c., are readily reproduced.

Open and Closed Magnetic Circuit Cores.—The cores for the coils used with the interrupter should naturally be of the open-magnetic-circuit type. They may approach the closed-circuit type, having a moderate air gap cut in them. Closed magnetic circuit cores may, however, be employed in the following way, devised by the writer: A polarizing winding, in addition to the other windings, is provided. It magnetises the core when the interrupter opens the circuit, oppositely to the effect of current in the winding in circuit with the interrupter or primary coil. The relations between the turns is such that the current through the interrupter overpowers the polarising current, the latter reversing the magnetism of the core at the time of interruption. The effect is similar to that of an alternating current in reversing the core magnetism rapidly. If a secondary coil be provided upon the same closed core its turns, sections, &c., can be adapted to the effect desired to be produced.

THE WORLD'S TELEGRAPH AND TELEPHONE WIRE.

The following table, giving the approximate mileage of the telegraphic and telephonic systems of the world at the end of 1898, was included in the Paper on "Telephones," read by Mr. John Gavey before the Society of Arts, on the 12th inst. It is compiled from official documents supplied to the Bureau International at Berne:—

	Lines.				Wire.			
	Telegraph lines.		Telephone lines of States and private companies.	Totals.	Telegraph lines.		Telephone lines of States and private companies.	Totals.

CORRESPONDENCE.

GOVERNMENT TELEPHONES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have just seen a cutting from your issue of the 7th inst., and I have to ask that you will kindly permit me to notice it. In doing so I know I am writing to a supporter of the Post Office Telephone Department and also of the National Company. In the paragraph in question you refer to an American correspondent having sent me the telephone rate at Baltimore. I said nothing about a correspondent having sent me this. I took the rate from a document used in the proceedings before the Senate Committee of the New York Legislation in February, 1895, in which it is stated that the £16 rate in Baltimore for a radius of two miles is a legal rate fixed by the Legislature. It does not mention whether the wires are single or double.

You say, "Mr. Provand appears to be quite unaware about the charges in Manchester, Liverpool and other large towns." I know the National Company's rates, so far as they publish them. Glasgow has a single-wire exchange. The rate is £10 within half-a-mile of the exchange, rising to £25 at greater distances. I have before me a receipt for £20 paid for a wire, the distance from the exchange being less than two miles. This, therefore, is far higher than the Baltimore rate. You say that the National Company in London charge £10 for private houses. I am writing from a private house to which they refuse to supply me with a wire for £10, and ask several pounds more. You do not appear to know the National Company's tariff.

I have taken no pains to convince you that the rates of telephone service in New York are maintained by corruption. I have simply quoted facts in connection with the proceedings taken before the State Legislature in regard to the rates. As a consistent friend of monopoly in this country you naturally support it in New York. There the rates are maintained by corrupt methods, here by the Post Office Telephone Department. The result is the same to the public, *i.e.*, extortionate rates and bad service. The remark in the last sentence of your note, to the effect that permitting municipalities to supply telephone service is not likely to lessen the danger of corruption, is simply an insult to our municipalities, by inferentially comparing them with Tammany in New York. Notwithstanding the opposition of the supporters of monopoly, and of the Post Office telephone blunderers, the Government Telephone Bill will pass and licences will be issued to such municipalities as ask for them and comply with the necessary conditions. The result will be that telephone service in this country will be as good and as cheap as it is in many other countries. I look for the departure of the National Company from Scotland altogether within a few years, from inability to compete in the supply of a good service at a fair price.—Yours, &c.,

A. D. PROVAND.

2, Whitehall-court, London, S.W., April 13, 1899.

[The Baltimore tariff we quoted is that charged at the present time. The English tariffs we quoted are those

Digitized by Google

charged to the majority of subscribers in the respective towns. We have not supported monopoly in New York, and have offered no opinion as to whether the telephone rates there are maintained by corrupt methods. Mr. Provand himself is responsible for introducing that element into the discussion—which must now close.—ED. *E.*]

AMERICAN NOTES.

NEW YORK, *April 8.*

Air Brakes for Electric Cars.—The Third Avenue Railroad Co. expects to brake their cars with a brake operated by compressed air, a slow-speed electric motor being used to effect the compression. The current will be automatically shut off when the air brake is applied.

Electrically-Operated Pumps.—Quite a number of cities are in the market for electrically-operated pumps for water supply.

The Rapid Transportation Question.—A scheme of greatest importance for this city, which has been the theme of fruitless discussion in engineering circles for years, is the providing of cheap and rapid transportation facilities for the people of the city. Only those who have to come and go on our elevated roads or surface lines, especially in the "crush" hours, have any idea of the discomfort attendant upon travel to and fro. A company, under the leadership of the Metropolitan Street Railway Co., offer to construct an underground rapid transit system. A proposition has been already submitted to the Rapid Transit Commission. The project involves the construction of a tunnel five miles long, to be followed by viaducts and tunnels alternating according to the configuration of the ground until the upper section is reached. It is proposed to make this distance at fast express speed, viz., 15min. The estimated cost is not given, though such figures as $200,000,000 have been mentioned.

Municipal Electricians.—The municipal electricians will hold a convention in this city September 4, at which it is said 180 cities will be represented.

Telephone Charges.—A strong fight has started in the United States against exorbitant telephone charges, and the legislatures of several States are taking a hand in it.

Briskness of Electrical Business.—The general business conditions are improving rapidly. The prosperity now prevailing is bringing out capital. The papers are full of announcements of new enterprises, of combinations, of consolidations, of advances in wages. The railway interests are enormous buyers, and are largely re-equipping the roads. Locomotive works are crowded, car shops are refusing orders, and, in fact, all manufacturing concerns are crowded with work. Copper has advanced under the heavy demand, but it looks as if it had reached high-water mark. The announcements of the discovery of new and rich copper deposits fill the daily Press. Boston and New York capitalists appear to be infatuated with the business. European interests also are in the rush for these properties, and some of them are undoubtedly of exceptional value.

LEGAL INTELLIGENCE.

Castner-Kellner Alkali Co. (Limited) v. Commercial Development Corporation (Limited).

The Master of the Rolls and Lords Justices Rigby and Vaughan Williams yesterday (Thursday) delivered judgment in this case on the appeal of the defendants from the order of Mr. Justice Bigham on August 3 last. The case has been fully reported in *The Electrician* of July 15 and 22, and August 2, 1898, and March 3 and 10, 1899. The action was brought by the plaintiffs, the registered owners of letters patent No. 20,259 (1894), granted to Carl Kellner for an invention of improvements in electrolytic apparatus for decomposing alkaline salts, and for an injunction restraining defendants from manufacturing or selling caustic soda or other alkali in infringement of these letters patent. The apparatus the defendants proposed to use was patented by M. Rhodin in 1896, and the plaintiffs alleged that this apparatus was in fact identical with one form of the Kellner patents, and their case was that the defendants had added nothing to the Kellner patent which was the one sued upon. Defendants, who denied the infringement, also attacked plaintiffs' patent on the ground of disconformity. Mr. Justice Bigham decided that the plaintiffs' patent was not bad on account of disconformity, and that the defendants had infringed their patent, and granted the injunction asked for. Hence the present appeal by defendants.

The MASTER OF THE ROLLS, in giving judgment, said that the action was brought for infringement of patent, but it was brought under very unusual circumstances. In the first place, the plaintiff's patent (Kellner's, 1894) had never been used for any commercial purpose, nor indeed, at all, except, perhaps, by way of experiment. Its non-use was not explained by the fact that, although new and novel, it had been superseded by a later invention. But such was not the case. The patent sued upon had not been used, because a prior patent belonging to the plaintiffs had been found to answer their purposes better; but this prior patent was not relied upon by the plaintiffs in the action. In the next place the defendants had not yet begun work, so that no infringement, in fact, by what they actually did could be proved. They had, however, constructed some apparatus according to another patent (Rhodin's, 1896), and they had admitted that they intended to use this apparatus; but it was obvious that, if in practice it were found desirable to depart from some of the directions contained in that specification, such departure might have a very material bearing upon the question whether the defendants really infringed the plaintiffs' patent. His lordship made this observation because Rhodin's specification referred to the slow rotation of one of its component parts, whereas it seemed plain that much better results were obtained by quick rotation of the same part. If defendants' apparatus were at work his lordship was satisfied by the evidence that the part to which he was referring would be rapidly and not slowly rotated. But if this were so, the effects produced would be so different that the question of infringement would, in his opinion, assume a totally different aspect. Again, when the defendants began to work they might find it better to keep what were called their bells stationary, and to rotate the trays and troughs in which they stood. They were under no obligation to work precisely as told by Rhodin. But if such modification were made the question of infringement would be totally different from what it was if they were to assume that the defendants intended to make no departure from the directions contained in Rhodin's specification. Again, when comparing the processes described in Kellner and Rhodin's specifications, Mr. Terrell made a very important admission in favour of the plaintiffs. He admitted that if there was no distinction between a rotary movement and a to-and-fro movement, described in Fig. 1 of Kellner's specification, then there was no practical distinction between his apparatus and plaintiffs'. This admission was not referred to by Mr. Justice Bigham, and it was very important, as plaintiffs' patent was for an apparatus and not merely for a method for making soda. But to treat this admission as an admission by the defendants as they would use it would necessarily amount to an infringement of the plaintiffs' patent, even if it was valid, appeared to him to be pushing the admission much further than was put to the learned counsel who made it, or to his clients, who would suffer the consequences of it. He paused there, to consider the first point which arose in this case, and that was the nature of Kellner's invention as disclosed in the specification. The invention was for an improved apparatus, and the real nature of that invention was quite clear. It was an apparatus for making an open-mouthed vessel containing an electrified solution of salt over a stationary layer of mercury, covered over fresh water. The vessel was to be moved in such a way that the electrified salt solution should be in contact with part of the mercury for a time and then be shifted to another part, whilst the mercury was acted upon by the salt water and converted into an amalgam of mercury and sodium, or be brought into contact with the fresh water, so as to decompose the amalgam into mercury and soda in solution. That was Kellner's invention, and, so far as he could judge, it was novel and useful. Kellner showed in his provisional specification one mode of carrying it out—namely, by a to-and-fro motion of the vessel or bell containing the salt solution; but it was quite competent for him to point out in his complete specification any better method of presenting the mercury first to the salt water and than to the fresh, provided he kept the mercury as quiescent as possible. His last point, therefore, was one of the essential features of his invention—the means of having a stationary mercury cathode, the shifting of the bell, and the non-shifting of the amalgam formed in it; the care taken to make openings in the lower ends of the bells, so as not to displace the mercury, and the descriptions showing how to work the apparatus whilst the mercury cathode itself remained at rest, so that the aim of the inventor was to keep the mercury as quiet as possible, consistently with the moving of the bells of salt water over its surface. This was very important, in order to distinguish Kellner's invention from Castner's prior invention, in which the mercury was moved rapidly from the mouth of one compartment containing salt water to the mouth of the other containing fresh water. His lordship had carefully studied Kellner's specification, and also the evidence of the experts called on both sides, and, notwithstanding what was said about there being no practical difference between moving a bell through mercury and moving mercury under a bell, he was satisfied that any process by which the mercury was intentionally moved or disturbed, otherwise than to the least possible extent, by moving bells of salt water over it, was outside and not fairly within Kellner's real invention as disclosed in his original specification. There he differed with Mr. Justice Bigham. His lordship did not attach importance to Fig. 6 in the complete specification, in which the position of the salt water and the fresh water were reversed. That was a modification consistent with the real invention described in the provisional specification. Further, he was not prepared to hold (especially having regard to the admissions made by Mr. Terrell, as already mentioned) that the mere substitution of a rotary motion for a to-and-fro motion of the bells would not be equally within Kellner's invention, as described in his provisional specification, provided, always, care were taken

Digitized by Google

to keep the mercury still; but the clause No. 3, and Figs. 7 and 8 to which it referred, was, in his opinion, an entire departure from the essential feature of his invention, as originally described. Here the mercury was intentionally not kept as still as possible, but might be moved and disturbed to any extent. This was quite inconsistent with the original idea. An invention for an apparatus for keeping the mercury still was not an invention for an apparatus for keeping the mercury moving. Clause No. 3. covered both inventions, and was such a departure and such an extension of Kellner's real invention as to render the patent sued upon invalid as it stood. Very possibly the defect could be cured by a disclaimer, but whether, when so cured, the patent would be infringed by the defendants it would be quite improper now to decide. If he was right in thinking that the defendants' apparatus could not be worked with advantage unless the mercury was kept in rapid motion and and not kept as still as possible, the plaintiffs would be well advised to reconsider their postion before they commenced a fresh action on an amended specification. In his opinion the judgment ought to be reversed, and judgment entered for the defendants with costs, and the plaintiffs must pay the costs of the appeal.

Lord Justice RIGBY concurred in a judgment of some length.

Lord Justice VAUGHAN WILLIAMS said he was in the unfortunate position of having to differ from his learned brothers. He explained his reasons for so doing in an exhaustive judgment, which he then withdrew.

Judgment was then entered for the defendants in accordance with the finding of the majority of the Court.

Radford v. Tasker and Sons.

At the Coventry County Court, last week, Mr. E. R. Radford, of Leicester, sought to recover £50 as commission from Messrs. W. Tasker and Sons, electrical engineers, Andover. Plaintiff said he was engaged by a manager for defendants to attend to their Coventry depôt at a fixed salary and a commission of 3 per cent. on all orders passing through the branch. Defendants denied that the person referred to had power to made the arrangement which plaintiff set up as justifying his claim. Judgment was eventually entered for plaintiff for £37. 10s., and costs.

PARLIAMENTARY INTELLIGENCE.

COUNTY OF LONDON AND BRUSH PROVINCIAL CO.'S BILL.

The Select Committee of the House of Commons, presided over by Sir William Coddington, which has had under its consideration a group of Bills relating to projects for extending the use of electricity, both for lighting and power purposes, in the Metropolis, resumed its labours on Tuesday.

Mr. PEMBER, Q.C., for the promoters, now stated that he wished to make an announcement which he thought might have the effect of shortening the labours of the Committee. It would be to some extent a complaint against the Board of Trade. Provisional Orders had been asked for by the promoters to give them power to supply electricity to the districts of Fulham, Battersea, Bermondsey, Rotherhithe, Lewisham, Lee, Greenwich, Eltham, Poplar, Bethnal Green, Hackney and Stoke Newington. These Orders were applied for months ago, but as late as April 4th, when the Committee, &c., were dispersed for the holidays, letters in regard to all these applications were received to the following effect :—

"Dear Sir: With reference to the application made by you on behalf of the County of London and Brush Provincial Electric Lighting Co. (Limited) for the above-mentioned Order, I am directed by the Board of Trade to state that they are not satisfied that the consent of the local authorities should be dispensed with in respect to any of the districts included within the area of supply."

It was not, therefore, the intention of the promoters to further proceed with the applications for these Orders, which were made in October last. The Board of Trade, therefore, could have, months ago, written the letter he had read, as they knew that the consents had not been obtained. He did not know whether it was possible for anyone to give the Board of Trade a wigging, but he only wished he could do it. (Laughter.) The promoters had written to the Board of Trade enquiring whether local inquiries could not be held, but the Board had made up their mind. The Bill would, in consequence, have to be amended, and the representatives of the various districts had been told that their further appearance before the Committee would be unnecessary. The promoters, would, however, still ask for powers to lay mains through Shoreditch, Bethnal Green, Islington, Whitechapel, Battersea and Lambeth.

Mr. WORSLEY TAYLOR, Q.C. (for the L.C.C.), said Mr. Pember's announcement had come to himself and his clients with great surprise, though he must leave his learned friend to settle his quarrel with the Board of Trade. What had taken place showed the exceeding inconvenience of the course adopted by the promoters in promoting a Bill, the lesser half of the objects of which were disclosed within its four corners, whilst the greater half were concealed. He did not know what attitude the L.C.C. would now assume towards the Bill.

The CHAIRMAN said the action of the Board of Trade in putting off their refusal of the Provisional Orders for so long seemed to the Committee rather discourteous, but they (the Committee) had no jurisdiction in the matter.

Counsel for a number of the petitioners against the Bill asked for costs, but the Committee reserved its decision on this point.

Mr. WORSLEY TAYLOR said he proposed to take no further action on the Bill, but to reserve the right of the L.C.C. to appear at a future stage. He would suggest, however, that it might be well for the Committee to throw out the Bill, so as to enable the promoters next year to come forward with a new and more carefully-considered measure. If the preamble were passed it would be well to put in the Bill a clause conferring on the L.C.C. powers of purchase.

Mr. STATHAM (for the Lambeth Vestry) asked the Committee to reject the application for a roving commission to open up the streets of Lambeth. At present there were three companies supplying electric light in the district, and in December, 1897, the Vestry had entered into an agreement with the promoters of the present Bill, under which certain privileges were conferred.

Mr. JOHN SMITH (vestry clerk of Lambeth) held that the fact that the Vestry had entered into an agreement with the promoters showed that there was no ill-will on the part of the Vestry. He objected to the proposal in the Bill to give the Board of Trade a veto as between the Vestry and the promoters in the matter of the opening up the roads.

Mr. C. TAGG (clerk to the Camberwell Vestry) pointed out that in return for consent to the proposals of the promoters in 1895, it was agreed that the Vestry should have powers of purchase. There were no purchase powers in the present Bill. There was no power under the existing purchase clause to purchase a generating station.

By Mr. PEMBER: Then, if you are not able to purchase the big generating station we propose to put up in Camberwell—which will be large enough to supply outside areas with energy as well as Camberwell—you would be in the same position after the passing of this Bill as you are in at present?—That is so.

The Order of 1896 gives you power to purchase the works authorised by the Order?—Yes; and though there is no generating station mentioned, we hold that there ought to be.

Mr. TALBOT (for the Camberwell Vestry) said, in 1895, the Vestry had gone very carefully into the matter, and had agreed to give consent to the promoting company's application for a Provisional Order, on the condition of the acceptance of the purchase clause, conferring on the local authority the right to acquire the undertaking after 21 instead of 42 years; and also the additional power to buy at any time, by paying £133 for every £100 of capital expended on the undertaking, with a 5 per cent. dividend on the capital of the company for the extra period. It was also contemplated that a generating station should be erected in Camberwell, proportionate to the demands of the district, but the company now proposed to erect a station of such dimensions that if at any time the local authority purchased they would be unable to acquire anything but the mains, as the station would be one supplying other districts as well. This he asked the committee to refuse its assent to.

Mr. E. MANVILLE, the consulting engineer to the Vestry of Shoreditch, testified to the crowded state of the roads in Shoreditch, owing to many large water and gas mains, together with the mains of the National Telephone Co., the Hydraulic Power Co. and others. In the last financial year the Vestry had supplied by their undertaking, 1,030,000 units of electricity in Shoreditch, of which 761,000 units had been taken by consumers. The cost of production was a little over 1¼d. per unit. This low rate was due to the fact that the heat generated by the destruction of the dust and refuse was used for the production of electricity. Only one quarter of the steam power required at the electric station was obtained by the use of coal. With the exception of the Edinburgh station the Shoreditch station was the most economically worked in the kingdom. Owing to the smallness of the area to be supplied—about one square mile—the service was carried out under favourable circumstances. He could not say whether the local rates were paid on the generating station. The accounts did not include interest on capital.

Dr. H. M. ROBINSON (clerk to the Vestry of Shoreditch) gave similar evidence, and stated that the electric undertaking was now paying rates the same as any other undertaking in the district. The electricity department was credited with 2s. for every ton of refuse destroyed.

The CHAIRMAN said he did not consider that the figure 1·28d., given as the cost per unit for the production of the electricity, was a fair one. A credit of 2s. per ton was given for destroying the dust; but the electric undertaking was not debited with anything for the use of the steam produced in so doing and used for generating purposes.

Mr. VESEY KNOX (for the Shoreditch Vestry) contended that that Vestry, having set up an electricity undertaking of their own at a cheaper rate than was the case elsewhere in the metropolis, were entitled to be treated with the greatest consideration. He asked the Committee to refuse the powers now asked for.

On Thursday the Committee met, and the CHAIRMAN said: The Committee do not think it necessary to hear further evidence in opposition to this Bill, as they have decided that they cannot pass the preamble. The applications made for costs the Committee have considered, and have decided not to allow.

Annual Meeting of the Verband Deutscher Electrotechniker.—The seventh annual general meeting of this Society has been arranged to take place in Hanover from June 8th to 11th. Members wishing to read Papers, or to exhibit apparatus, &c., are requested to communicate with the Secretary at 8, Monbijouplatz, Berlin, N., as soon as possible, and to state, at the same time, whether their Papers will be illustrated by experiments. The Papers themselves should be sent in by the middle of May at the latest.

ELECTRIC LIGHTING SCHEMES FOR THE CITY OF LONDON.

On Tuesday Sir Courtenay Boyle, K.C.B., resumed the inquiry into the applications for Provisional Orders for the supply of electric current to the City of London area, made by the Charing Cross and Strand Electricity Supply Corp. (Limited), the Metropolitan Electric Supply Co. (Limited), and the Smithfield Markets Electric Supply Co. (Limited). The counsel employed in the enquiry were the same as set out in our issue for March 31.

At the commencement of proceedings Sir COURTENAY BOYLE asked whether the Corporation proposed to submit evidence from the City engineer.

Mr. GRAY (for the Corporation) explained that at a meeting of the Court of Common Council, held the previous day, a series of resolutions were passed, the effect of which was that the City engineer would be called.

Mr. D. J. ROSS said he was associated with the late Col. Haywood in the first installation of electric light in the City in 1870. He was familiar with the laying of the mains in the City in 1890-92, and knew that the work seriously interfered with the traffic and caused a great amount of public inconvenience. The operations were on a very large scale, and £30,000 was spent in relaying pavements. He believed the cost of electric current would be cheapened if there was competition within the City. In nearly all cases the space beneath the footways in the City were filled with pipes and tubes, and if other mains were laid they must be placed beneath the carriage way, a fact which would add to the public inconvenience. Under the agreement with the City of London Company the Corporation claimed 1d. a lamp in case of a failure. The fines paid by the company in 1892 came to £119, in 1893 £136, in 1894 £138, in 1895 £137, in 1896 £362, in 1897 £352, and in 1898 £156. Unless all the circumstances connected with that competition were known it was difficult to express an opinion as to the public advantage to be derived from competition.

Mr. POPE (for the City of London Company) said the attitude of the City Corporation was one of the most important factors in the question, and he assumed that this attitude was correctly described by the resolutions which that body had adopted on the previous day. He would not discuss the question whether the agreement between the company he represented at that inquiry and the late Commission of Sewers was a valid agreement or a binding one, that was a matter between the Corporation and the City Company. He contended that the consent of the local authority to a Provisional Order was a condition precedent to the granting of the Order, and that there must be special circumstances to induce the Board of Trade to pass over such consent. The advantages of competition did not constitute such special circumstances, as this was common in every case. The resolutions adopted only the previous day by the Corporation surely meant that the City desired to be left alone, the existing arrangements being undisturbed. If the agreement between the Corporation and the City Company had been rendered void, the position of both bodies was an awkward one, as some of the most onerous conditions were determined, not by the Provisional Order of the Company, but under the agreement. Among other matters was the question of street lighting, which was determined, not by the order, but by the agreement. No case had been made out against the City Company. The service could not be a bad one, as in the public supply the occasional default had involved a penalty of only £36 in six months upon a total payment of £12,000. This could not, he urged, be held to justify the Board of Trade in disturbing the relations between the local authority and the City company.

Mr. FITZGERALD (for the Metropolitan Company) said the Corporation had acted consistently throughout, and it was obvious from the resolutions just adopted that it desired to leave the matter in the hands of the Board of Trade to be dealt with in manner it might think best for the public interest. He asked the Board of Trade to say that the Metropolitan Company was the most capable of the three applicants to compete with the existing supply within the City.

Mr. SHIRESS WILL (for the Charing Cross Company) contended that the Corporation clearly meant by its resolutions that the Board of Trade should not stand still, as nothing could be gained by such action.

Mr. BALFOUR BROWNE (for the Smithfield Markets Company) said his clients were best able to supply the City and to meet the wishes of the Corporation, as they were the only one of the three applicants already within the City district.

Mr. GRAY said he was instructed to state that the Corporation did not recognise the Smithfield Markets Company in any shape or form. The Corporation desired to take a position of absolute neutrality in the matter in accordance with a resolution passed on Feb. 23.

Sir COURTENAY BOYLE said the inquiry would now close. The subject would receive the utmost careful consideration of the Board of Trade, which would communicate with the Corporation before coming to any decision.

THE CITY OF LONDON ELECTRIC LIGHTING CONTRACT.

A special meeting of the London Common Council was held on Monday to receive reports as to the legality of the contract with the City of London Electric Lighting Co. and also as to the attitude to be observed by the Council at the Board of Trade inquiry into the applications of three electricity supply companies for Provisional Orders for the City district. After having decided to discuss the matter with open doors, the report of the City Solicitor, embodying the opinion of counsel (Mr. W. O. Danckwerts), was read by the Town Clerk. The Streets Committee now recommended that this report and opinion should be referred back to them, with authority to take further opinion of counsel. The solicitor stated that the question had reference to the alleged breach of section 42 of the Sewers Act (1848) by Alderman Sir Joseph Savory, who had become interested, as a shareholder in the Brush Company, in the electric lighting contracts entered into by the Commission of Sewers and that company. Mr. Danckwerts was of opinion that section 42 of the 1848 Act was still in force and applied to the Corporation, to whom the powers of the Sewers Commission had been transferred. He was of opinion that the section was operative not only with regard to the time at which the contract was made, but to the whole currency of the contract, so that a contract would even be affected by an alderman or common councillor becoming concerned or interested therein after it had been made or entered into. Cases had been before the courts which settled this point, and from these decisions it was clear that a shareholder in a company was so interested or concerned in a contract made with the company in which he was a shareholder, the result being that section 42 of the Sewers Act rendered null and void any contract made between the Sewers Commission and a company which during the currency of the contract had as a shareholder anyone who was a commissioner of sewers or an alderman or councillor. Sir Joseph Savory was a shareholder in the Brush Co. apparently during the currency of contracts with the commissioners, and the contracts so became null and void. He appeared also to have been a shareholder in the existing City of London Electric Lighting Co., as were also other commissioners and common councilmen; and the contracts between the Corporation and the Company were, in his (Mr. Danckwerts) opinion, null and void. If that were so, they could be set up either by fresh contracts or by legislation. The matter might be legally tested by bringing an action against the Company for a declaration, and it might also personally be tested by proceeding for penalty. The City solicitor said if the Corporation were satisfied with Mr. Danckwerts' opinion, and did not deem it necessary to have it justified by that of one of Her Majesty's counsel, the Corporation ought to take immediate steps in the matter. Of course, the opinion was not binding on the City of London Company, and it was not likely that the Company would for one moment admit its accuracy. Should an immediate test be deemed desirable, it would be an easy matter to ask the opinion of a court of law on the subject. If, on the contrary, the Committee were of opinion that advantage ought not to be taken of what was considered by some a technical breach, and by others a serious breach of the statutory provisions alluded to, the Company would still have to be approached with a view to an early removal of the disability under which the Company was working, supposing the opinion he had read to be correct. Mr. Algar, who moved the adoption of the report, and, further, that it should be referred back to Committee in order that further legal opinion might be obtained, said the majority of the Committee was satisfied with the opinion. During the conference with counsel a question was raised as to whether, if a member of the Court had taken at any time a share in the City Company, the contract would become null and void, and counsel replied: "Certainly; but the Company has it within its power to pass a resolution to the effect that no member of the Court of Common Council should be capable of holding shares in the Company." Having regard to the serious position in which the Corporation was placed the Committee now asked the Court to allow them to take the opinion of a Queen's counsel in order to ascertain whether Mr. Danckwerts' opinion would be confirmed. Mr. Alpheus Cleophas Morton made a lengthy speech. He said the characters of the members of the Court of Common Council should be kept clear of all conspiracies and all improper acts, and he hoped the time had come when the Court could deal with the City Company, who had acted so wrongly with the Court. The Company commenced by surreptitiously putting down pipes in the City streets for the purpose of letting them to the National Telephone Co. If the commissioners had done their duty they would have compelled the Company to pull them all up again. The report was then adopted and the Committee was authorised to obtain a further opinion.

The next matter discussed was the report of the Streets Committee relating to the Board of Trade inquiry, and to the request of Sir Courtenay Boyle, K.C.B., to be furnished with the views of the Corporation and the evidence of the engineer with regard to the three applications for Provisional Orders to supply electricity within the City. It was recommended that the following propositions should be adopted:—

(*a*) That evidence be tendered, on the resumption of the inquiry, by the engineer and by the electrical engineer.

(*b*) That if, notwithstanding the terms of the agreement with the City of London Electric Lighting Co., the Board of Trade see fit to exercise the power conferred upon them by section I. of the Electric Lighting Act (1888), this Court is of opinion that the Board should not grant more than one Provisional Order, as a multiplication of the systems of supply would be prejudicial to the interests of the Corporation when the time came to take over the undertakings.

(*c*) That this Court is of opinion that the Board of Trade should not dispense with the consent of the Corporation unless in the case of an applicant who is prepared to accept the insertion in the Provisional Order of such terms and conditions as will secure the immediate and future interests of the private consumers and the public.

(*d*) That, should the Board decide to grant competition in the City, it should be subject to the Corporation having the right to purchase the undertaking (whether within or without the City) on terms to be previously agreed upon.

(*e*) That provision should be made in any Provisional Order to guard against the possibility of combination between two competing undertakers.

After considerable discussion it was decided not to give expert evidence at the inquiry, and to inform Sir Courtenay Boyle that the Corporation did not desire to express any preference for any one of the companies. Recommendations (*c*), (*d*) and (*e*) were then adopted without debate.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.*]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

NOW READY.

"Laboratory Notes and Forms."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"Electrical Testing for Telegraph Engineers."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

"The Students' Guide to Submarine Cable Testing."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"Submarine Cable-Laying and Repairing."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"Practical Notes for Electrical Students."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"Electro-Chemistry."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"Electric Motive Power," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s. *New edition ready May 1, 1899.*

"Wireless Telegraphy: Signalling across Space without Wires by Electric Waves."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"Electromagnetic Theory."—By Oliver Heaviside *Vol. I.*, 12s. 6d. *Vol. II. ready May 1, 1899.*

"The Incandescent Lamp and its Manufacture."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"The Steam Engine Indicator and Indicator Diagrams."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"The Art of Electrolytic Separation of Metals."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"The Manufacture of Electric Light Carbons."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated, price 1s. 6d.; post free, 1s. 9d.

"The Bibliography of X-Ray Literature and Research, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of genera as well as special information bearing upon the whole subject of electrica discharge research. Price 5s., post free; abroad, 5s. 3d.

"Localisation of Faults in Electric Light Mains."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"Electrical Engineering Formulæ," a pocket-book, by Messrs. W Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"The Alternate Current Transformer," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"Electric Lamps and Electric Lighting," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"The Electrician" Primers.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 3d. each, post free.

"The Potentiometer and its Adjuncts": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s. post free; abroad, 6s. 6d. Digest post free.

"Drum Armatures and Commutators," by Mr. F. Marten Weymouth also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"Motive Power and Gearing for Electrical Machinery."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

"Armature Windings of Electric Machines."—By H. F. Parshal and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

IN THE PRESS.

"The Electric Arc."—By Mrs. Ayrton.

"The Manufacture of Carbons for all Electrical Purposes."—By Francis Jehl.

"Electromagnetic Theory."—By Oliver Heaviside. *Vol. II. ready May 1, 1899.*

"Secondary Batteries, their Design and Manufacture."—By E. J. Wade.

"Primary Batteries: Their Construction and Use."—By W. R Cooper.

"Practical Telephony."—By Dane Sinclair and F. C. Raphae

"'The Electrician' Wireman's Pocket-book."—By F. C. Raphael.

"The Electrician" Electrical Trades' Directory and Handbook for 1899.—The "Big Blue Book" for 1899 is Now Ready. The Directory Division has been corrected up to Feb. 8, 1899, and all the latest new names, changes of address, &c., will be found included. The Handbook Division has been much extended, many valuable tables having been added. The volume contains, also, the large Sheet Tables of Electricity Supply Stations and Electric Railways and Tramways, finally corrected to Feb. 9, 1899. The price of the Directory and Handbook remains the same—10s., post free 10s. 9d.; abroad, post free, 12s. (United States 13s. 6d.).

TENDERS INVITED.

As advertised elsewhere, the *Epsom* District Council invite tenders for the supply and erection of: (*a*) Lancashire boilers and fittings, economiser, feed pumps, &c.; (*b*) pipework, &c., in engine and boiler house; (*c*) steam dynamos and motor boosters; (*d*) storage batteries; (*e*) main switchboard and connections; (*f*) overhead travelling crane; (*g*) underground mains and conduits; (*h*) arc lamps and posts; (*i*) street glow lamps and accessories; and (*k*) station lighting. Specifications, &c., may be obtained from the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C., on and after the 10th inst. Tenders to the clerk (Mr. E. G. Wilson), High-street, Epsom, by noon of May 8.

The *Hampstead* (London) Vestry invite tenders for the supply of two 500-kilowatt steam alternators, five Ferranti or similar type switchboard panels, boilers, feed-water heaters, feed pumps, a 40-kilowatt exciter, water softening plant, air pump and condenser, economiser, overhead travelling crane, &c. Further particulars are set out in an advertisement, and specifications, &c., may be obtained at the office of the clerk (Mr. Arthur P. Johnson), Vestry Hall, Hampstead, N.W., where tenders must be lodged by noon of May 18.

The Electric committee of *Belfast* invite tenders for mechanical stokers, economisers, pipe work and condensing plant. Specifications, &c., may be obtained from the city electrical engineer (Mr. Victor A. H. McCowen). Further particulars are given in an advertisement, and tenders must be sent in to the town clerk (Sir Samuel Black) by noon of Thursday, April 20.

The *Belfast* Electric committee also invite tenders for laying conduits and building junction boxes and for laying cables. An advertisement contains further particulars. Specifications, &c., may be obtained from the city electrical engineer (Mr. Victor A. H. McCowen), and tenders must be lodged at the office of the town clerk (Sir Samuel Black) by noon of Thursday, 27th inst.

The Town Council of *Reigate*, Surrey, require tenders for (1) two water-tube boilers, economiser, brickwork, and flues, (2) steam exhaust and other pipes, steam pumps, &c., (3) two 100 kilowatt and one 20 kilowatt steam alternator, 8-ton overhead travelling crane, and sub-station equipment, (4) switchboard and instruments, (5) mains, lamp-posts, lamps and fittings. Specifications, &c., can be obtained from Mr. F. Hastings Medhurst, consulting engineer to the Council, 13, Victoria-street, London, S.W., on and after April 10, and sealed tenders must be delivered to the town clerk (Mr. Clair J. Grece), 84, Station-road, Redhill, Surrey, not later than noon of Monday, May 1. An advertisement on another page gives further particulars.

As advertised elsewhere, the *Salford* Electric Light committee invite tenders for the supply of 3,220 yards of 0·2 high tension concentric lead-covered cable, compound insulation. Specifications, &c., may be obtained from the electrical engineer (Mr. Chas. L. Turner), Walness-road, Broughton. Tenders (addressed to chairman of Electric Light committee) must be delivered at the office of the town clerk (Mr. Samuel Brown), Town Hall, Salford, by 9 a.m. of Friday, 28th inst.

Digitized by Google

The *Darlington* Corporation invite tenders for the supply and erection of:—(1) Lancashire boilers, with mechanical stokers; (2) engines, dynamos, pumps, pipes, &c, Green's economiser and tools; (3) storage battery; (4) switchboard and boosters; (5) arc lamps; (6) feeders, mains and arc light leads, including roadwork. Further particulars are given in an advertisement. Plans and specifications can be obtained at the office of the borough surveyor. Plans can also be seen at, but not obtained from, the office of the consulting engineer (Prof. Alex. B. W. Kennedy), 17, Victoria-street, London, S.W., and tenders must be lodged with the town clerk (Mr. Hy. G. Steavenson), Town Hall, Darlington, by May 8.

As advertised elsewhere, the *Edinburgh* Corporation invite tenders for twelve months' supply of:—(1) steam coal, (2) arc lamp carbons, (3) cast iron pipes, pavement box frames, &c. Specifications may be obtained from the borough electrical engineer (Mr. F. A. Newington), 5, Dewar-place, and tenders must be lodged with the town clerk (Mr. Thos. Hunter, W.S.), City Chambers, Edinburgh, not later than 24th inst.

The Vestry of the parish of *St. Mary, Battersea* (London), require tenders for the supply and erection of (1) feeders, distributing mains, and arc light leads (including laying and jointing); (2) watertube boilers; (3) steam dynamos and engines. Further particulars are given in an advertisement, and specifications, &c., may be obtained from the vestry clerk (Mr. W. Marcus Wilkins), Municipal-buildings, Lavender-hill, London, S.W. Specifications and drawings may also be seen at, but not obtained from, the office of Prof. Alex. B. W. Kennedy, 17, Victoria-street, London, S.W., and tenders must be sent in to Mr. Wilkins on or before noon of Wednesday, June 7.

The *South Shields* Corporation require tenders for steam and water pipes and valves and a 15-ton hand-power overhead travelling crane. Tenders to town clerk by 20th inst.

The *Poplar* (London) District Board of Works invite tenders for engine and pump room equipment and all electrical plant except battery; boiler house equipment; battery and battery stands; and public street lighting. Tenders to Mr. Potts by 10 a.m. April 25.

The *Tynemouth* Corporation invite tenders for boilers, &c., economisers and fittings, ejector-condenser, circulating pumps, tanks and pipework and water cooler, pumps, feed pipes, &c., travelling crane, traction switchboard, lighting switchboard, accumulators, cables, and traction steam dynamo. Tenders to the town clerk by noon of April 15.

The Great Northern Railway Co. (Ireland) invite tenders for cables for feeders, returns, potential lines, &c., 6 motor and 6 trailer cars, overhead construction, and battery and booster. Tenders to secretary by April 20.

The *Peterborough* Corporation invite tenders for the supply and erection of Lancashire boilers and economiser; steam dynamos, balancers and boosters; secondary battery and accessories; switchboard and instruments; piping, tank, condensers and pumps; and insulated cables. Tenders to town clerk by April 20.

The *Hull* School Board invite estimates for the installation of the electric light at the central higher-grade school and school of science. Tenders to clerk by 25th inst.

The *West Ham* Council invite tenders for two 1,500 I.H.P. engines, two 800 kilowatt alternators and exciters, Tenders to town clerk (Mr. Fred. E. Hilleary) by 4 p.m. of April 25.

The Gas and Electricity committee of the *Stockport* Corporation require tenders forstorage battery of 750 ampere hours' capacity. Tenders (addressed to chairman) by 19th inst.

The *Reigate* Town Council invite tenders for the electric lighting of their proposed isolation hospital. Particulars from surveyor, and tenders to town clerk by 19th inst.

The *Dublin* Corporation invite tenders for the supply, fitting and connecting of electric light fittings suitable for a 200 volt supply. Specifications from city engineer and tenders to town clerk by 20th inst.

The municipal authorities of *Almodóvar del Campo*, Ciudad Real, Spain, require tenders for the electric lighting of the streets for 20 years. Tenders by May 5.

TENDERS RECEIVED AND ACCEPTED.

The Gloucester Town Council, at their last meeting, considered reports of the Electricity Supply committee and the consulting engineer (Mr. Robert Hammond), and accepted the following tenders for additional plant required for the electricity works :—

British Insulated Wire Co. (public arc lighting)	£969 16
Blake and Knowles (condensers and air pumps)	567 0
Stanton Ironworks Co. (cast iron water pipes)	400 0
Ashton, Frost and Co. (steel steam, exhaust pipe and drain pipes)	1,185 0

The Aberdeen Town Council have accepted the tender of Messrs. Macartney, McElroy and Co. for the supply of overhead line construction, tram-cars and accessories, switchboard, instruments, &c., for the Woodside electric tramway, at £7,793. The tender of the British Insulated Wire Co., for feeder, pilot and test cables, has been accepted at £5,340. Including the contract for the permanent way and road work, the whole of the contracts amount to £32,153.

The Canterbury Council have accepted, on the recommendation of the Lighting committee and their consulting engineer (Mr. Robert Hammond), the following tenders for additional plant and mains :—

R. Taylor and Sons (one boiler complete and mechanical stokers)	£707 10
India Rubber Company (one 150 kilowatt steam dynamo, steam, exhaust, &c., pipes, condenser, and accessories, centrifugal pump and motor, tools, painting, &c.....	2,622 0
Western Electric Co. (underground mains, cables, &c.)	1,314 0

The tenders for switchboard extension are still under consideration.

The Bury (Lancs.) Town Council have accepted the following tenders :—

Ashton, Frost and Co., for the supply and erection of three electric motors at the sewage works. Eighteen tenders were received.

W. Lord, for the supply and erection of Lancashire boiler with steam and other pipes. Two tenders received.

Scholes and Sons, for the wiring of the sewage works. Twelve tenders received.

The following tenders have been obtained by the Fulham Vestry for the supply of generating plant, mains, &c., in connection with their electric lighting scheme, and have been referred to the Electric Lighting committee and the consulting engineer (Mr. F. H. Medhurst) for analysis and report :—

British Insulated Wire Co.....	£51,542	8	6	S. Z. de Ferranti (Limited)	£49,339	17	2
John Fowler & Co...	50,815	2	6	Brush Co.	47,282	0	0
Johnson and Phillips	49,927	6	0	General Electric Co.	45,718	7	10

The tenders were not publicly invited, the above firms being asked to submit estimates privately.

The following tenders were accepted by the Hammersmith (London) Vestry at their meeting on Wednesday evening :—

Babcock and Wilcox, three water tube boilers, £3,320.
J. Musgrave and Co., two vertical steam engines, £7,284.
Siemens Bros. and Co., two alternators, £5,684.
Callender's Co. cables, at schedule prices.
James Ritchie, cast iron pipes at schedule prices.

The Liverpool Corporation have extended the contract with the Callender company for the supply, laying and maintenance of electric light mains for two years.

The Burton Town Council have accepted the tender of Tinkers (Limited) for the supply of additional boilers at the electricity works for £1,980. Originally the Council were recommended to accept the tender of Messrs. Edwin Danks and Co., but the labour members objected to the acceptance of the tender as they alleged the firm did not pay the standard rate of wages. The actual result is that the Council pays £285 more by the acceptance of a fresh tender. The tender of Messrs. Westwood and Wright has also been accepted for the supply and erection of ironwork at the station.

The Rothesay Town Council have accepted the tender of Messrs. Lowdon Bros. for the supply and erection of two 20 H.P. coupled engines and dynamos, switchboard, cables, arc lamps and posts, feed pumps, steam and exhaust pipes, &c., at £2,501. 19s. 2d.

The tender of Messrs. James Carrick and Sons has been accepted by the Brighton Town Council for the supply of a 20-ton travelling crane at the electricity works at £415. Messrs. Carrick and Ritchie also tendered at £498.

The Dundee Tramways committee recommend the Council to accept the following tenders :—Cooper and Greig, four Lancashire boilers and seatings, £3,058; Lowdon Bros., two 450 H.P. steam dynamos and one 700 H.P. steam dynamo, £9,700. The steam dynamos are to be Willans'—Thomson-Houston sets.

The Plymouth Town Council have accepted the tender of the Edison and Swan Co. for the supply of sub-station transformers at schedule prices, and arc lamp carbons at £5 per 1,000 pairs. The tender of the Brush Co. for the supply of street-box transformers at schedule prices has also been accepted.

The Winchester Town Council have accepted the tender of Messrs. E. H. Gudgeon and Co., for wiring the public offices, public library and art school, at £214. 7s. 8d.

APPOINTMENTS VACANT AND FILLED.

The Gas committee of the Keighley Corporation require an electrical engineer to prepare specifications, &c., of an electric lighting scheme. Further particulars are given in an advertisement, and applications (addressed to the chairman of the committee) must be sent to the town clerk (Mr. George Burr) by May 1.

The Leyton District Council require a draughtsman for their electricity department to work under the instructions of the Council's chief electrical engineer. Salary £100 per annum, rising to £150. Some further particulars will be found in an advertisement. Mr. R. Vincent, Town Hall, Leyton, is clerk to the Council.

The Belfast Electric committee require an assistant electrical engineer. Further particulars are given in an advertisement, and applications must be lodged with the city electrical engineer (Mr. Victor A. H. McCowen), Central Station, East Bridge-street, Belfast, by Tuesday, 25th inst.

Digitized by Google

The Salford Corporation require an assistant electrical engineer. Salary, £160 per annum. Applications (addressed to chairman of Electric Light committee) must be delivered at the office of the town clerk (Mr. Samuel Brown) before 9 a.m. of Tuesday, 18th inst. See advertisement.

The Hull Electric Lighting committee require two junior assistants. Applications to city electrical engineer (Mr. A. S. Barnard), Electric Light Station, Dagger-lane, Hull, by April 20. See advt.

The Sheffield Corporation require a mains superintendent, at a salary of £250 per annum. Applications to the manager and engineer (Mr. Wm. Johnson), by 27th inst. See advertisement.

The Central London Railway Co. require a traffic superintendent and an accountant. Applications to secretary, 16, Great George-street, S.W., by 29th inst.

Mr. H. Haskayne, assistant superintending engineer of the South Wales district Postal Telegraphs, has been appointed superintending engineer of the North Western district at Manchester, in succession to Mr. John Doherty, who recently retired. Mr. Haskayne joined the old United Kingdom Telegraph Co. at Liverpool in 1863, and after six years' service went to Leeds, where he remained until 1870. When Government took over the telegraphs Mr. Haskayne was transferred to the commercial branch, but in 1874 he was appointed to the engineering department. In 1892 he was promoted to the position of assistant superintending engineer of the South Wales district under Mr. J. Gavey.

Dr. J. T. Nicholson, of Montreal, has been appointed lecturer in the engineering department of the Manchester Municipal Technical School.

BUSINESS NOTICES.

Under the title of the Helios Electrical Construction Co., a company has been formed to represent in this country the well-known firm of Helios, Cologne, one of the oldest electrical concerns in Germany. The company has offices at 49, Cannon-street, E.C., and has appointed Mr. A. C. Eborall (who was at one time with Messrs. Brown, Boveri and Co.), as their chief engineer. We are informed that the company will have special facilities for quick deliveries of lighting and power plant.

Owing to the parliamentary and preliminary work in connection with the Midland Electric Corporation for Power Distribution being nearly complete, Mr. G. L. Addenbrooke has closed his Wolverhampton office, and future communications should be sent to 53, Victoria-street, London, S.W.

Messrs. Pratt and Keith, of Aberdeen, have added an electrical department to their business, and Mr. Alex. Lindsay has been appointed electrical engineer.

BANKRUPTCIES, LIQUIDATIONS, &c.

The following are among the creditors in the bankruptcy of Daniel W. Paine, electrician, 84, Gloster-road, Brighton :—

A. Bunting	£33	General Electric Co.	£16
Fuller and Co.	30	H. M. Salmony and Co.	15
Crystal Lamp Co.	28		

The liabilities are returned at £162. 3s. 8d.

At a meeting on 5th inst., at 31, Bedford-row, London, W.C., it was resolved to wind up the Electrical Time Recording Co. (Limited) voluntarily. Mr. A. B. Clifton is liquidator.

Claims against R. C. Douglas, of Mayfield, Urban-road, Sale (formerly trading as the Manchester Electric Co. at Haworths-buildings, Cross-street, Manchester), must be in by 21st inst. Mr. C. J. Dibb, Byrom-street, Manchester, is trustee.

Electrical Standardizing, Testing and Training Institution.—The new session of this institution has just commenced. Particulars of the course of study will be found set out in an advertisement on another page.

Electric Launches.—Messrs. Laing, Wharton and Down will supply, post free, a well illustrated brochure describing the "Vril" launches, motors, controllers, &c. The particulars given will prove especially interesting to yacht owners.

The "Engineering Magazine."—The contents of the April issue of this magazine include: "Commercial Aspects of Electric Traction in Great Britain;" "America and Germany as Export Competitors and Customers;" "Machine-shop Management in Europe and America;" "The Monitor, the Battleship, the Cruiser, and the Destroyer;" "The Merits and Permanency of the Masonry Arch Bridge;" "The New Terminal of the Orleans Railway at the Quai d'Orsay;" "Depreciation as an Element of Machine-shop Cost-keeping;" "The Development of Wood-working Machinery;" "The Prospective Expansion of American Shipbuilding;" and "The International Association for Testing Materials." The usual review of the engineering press is also given. Copies of the magazine may be had at 1, 2 and 3, Salisbury-court, Fleet-street, London.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from March 31 to April 11, with the ports of destination :—

Argentina—Buenos Ayres, £1,875 (including £517 telegraph material); *Australasia*—Melbourne, £773 (telegraph material); Nelson, £115 (telegraph material); Newcastle, £480; Sydney, £2,753 (including £741 telegraph material); Wellington, £1,962 (including £1,715 telegraph material); *Belgium*—Ostend, £116. *Chili*—Boca, £15. *China*—Shanghai, £295. *Denmark*—Copenhagen, £49. *Egypt*—Alexandria, £5. *France*—Boulogne, £18. *Germany*—Hamburg, £110. *Holland*—Amsterdam, £20. *Hong-Kong*, £182. *India*—Bombay, £311 (including £133 telegraph material); Calcutta, £430; Madras, £330 (including £134 telegraph material). *Japan*—Yokohama, £390. *Java*—Ballek Pappen, £290 (telegraph cable). *Malta*—£1,501 (including £1,450 telegraph instruments). *Portugal*—Lisbon, £80 (telegraph material). *South Africa*—Cape Town, £523; Durban, £1,248; East London, £3,461; Port Elizabeth, £1,045; Zanzibar, £26 (telegraph material). *Straits Settlements*—Singapore, £171 (including £132 telegraph material). *Sweden*—Stockholm, £780 (telegraph material). *West Indies*—Trinidad, £13. Total (for 12 days) £19,367, against £16,127 for two days last year (April 6 and 7).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

All-British Cable Schemes.—In *The Times* of April 1 there appeared a letter signed "Colonial," which contained the following statement, among others :—

"Some years ago the Pender group effected an amalgamation of office in Hong Kong, with the Great Northern Telegraph Co. of Copenhagen, whose cable connects with the Russian Government Telegraph Administration. It would seem that the Danish Company handed over its right in that agreement to Russia, inasmuch as the Company's representative in London declared in an interview some months ago that the cable worked from the joint office and introduced as a Danish cable is now Russian property. Consequently the Pender group are responsible for the existence of this dangerous anomaly—that Russian officials are admitted to an important telegraph office, in an outpost of the empire, through which all telegraphic communications with our Government, public, and Press must necessarily pass! There, at any rate, the door is wide open. It will not do for the Pender group to plead ignorance of the intimate relations existing between the Danish Company and the Russian Government; that was a matter of common knowledge in China long before the amalgamation."

Mr. F. C. C. Nielsen, representative of the Great Northern Telegraph Co. in this country, has replied as follows in *The Times* of the 11th inst. :—

"The letter of April 1, signed 'Colonial,' states that the Great Northern Telegraph Co.'s 'representative in London' declared in an interview some months ago that the cable worked from the joint office (in Honk Kong), and introduced as a Danish cable, is now Russian property. Permit me to point out—first, that I am not aware of having had any 'interview' with anybody on the subject referred to for a whole year, or not since April, 1898, and the gist of my observations on that occasion to a representative of the *Westminster Gazette*, as quoted in that paper of April 27, 1898, was quite the reverse of the statement attributed to me by 'Colonial'; secondly, that I never made, nor could have made, any such statement—(1) because, as pointed out at the said interview, one of the very objects of the joint working arrangement of the two companies in the Far East was to leave the leadership and control of the Hong Kong station to the British Company (the Eastern Extension Telegraph Co.); (2) because the cable from Hong Kong to Amoy, and further to Shanghai, Japan and Siberia is and always has been the property of the Danish Company (the Great Northern Telegraph Co.), in whose service there is not a single Russian, but a number of Englishmen, and whose shares are more largely held in this than in any other country, while not a single share is held in Russia. As to the relations of the Company with foreign Governments, they are, happily, as intimate with the British as with the Russian and other Governments on whose territories our cables are landed. The other invidious insinuations of 'Colonial' I may safely leave unanswered; they are beneath notice."

It is announced that the Canadian Government has decided to introduce a Bill by which Canada agrees to pay $\frac{5}{8}$ths of the cost of laying a submarine telegraph cable from Vancouver to Sydney, so soon as the Imperial Government is prepared to contribute a similar proportion, leaving the Australian colonies to complete the cost. Sir Charles Tupper and Sir M. Bowell have jointly congratulated the Canadian Premier (Sir William Laurier) on the Government proposals.

Argentina.—In a report on the trade of the Argentine Republic for 1898 attention is drawn to the great progress of electric lighting and power schemes in Argentina. Buenos Ayres is crossed and recrossed by electric tramways, and three extensive electric lighting concerns have been established—one British, one German and one French, making four companies in the Buenos Ayres district, all in full working order. The two electric tramway companies are both British, but a German company has recently bought up the Metropolitan Tramway Co. and intends to convert the line into an electric one. The number of passengers carried on the Buenos Ayres tramways in 1898 numbered 106,000,000, while the railway running into the city carried only 11,000,000 passengers.

Digitized by Google

Bath.—By a narrow majority of one the question of constructing electric tramways has been shelved by the Surveying committee.

Blackburn.—The Council have decided to apply for sanction to borrow a further £25,500 for electric lighting and tramway purposes, to cover the requirements of the lighting and tramway department during the present year.

Bootle.—The date of the formal opening of the electricity works has been fixed for the 20th. The Electric Light committee intimate that they hope to bring forward at the next council meeting a scheme for the supply of current throughout the borough.

Bournemouth.—The Board of Trade have intimated to the Council that they are prepared to grant them a provisional order for public lighting only. The Town Clerk has been instructed to urge the Board to grant the order as drawn, and, if necessary, to hold a local inquiry.

Bradford.—At a meeting of the Bradford and District Trades and Labour Council, held last week, a delegate from the Electrical Trades Union asked for assistance in fixing a standard rate of wages for electric wiremen, who, in Bradford, were said to be in a very poor way in regard to wages. Some of the largest firms in the town (the delegate asserted) paid the least wages. The men thought that 8d. an hour was quite little enough, but they had had to accept 4½d. Electric light wiremen had to keep themselves respectable, and were liable to be called upon to work in very different places—from a coal mine or a workshed to a gentleman's house. The average wages paid to wiremen in other towns were considerably in advance of those paid in Bradford, and in Leeds and Manchester it was 8½d. per hour. Mr. Hayhurst said every electric light wireman who came into Bradford had to obtain the permission of the Electricity committee of the City Council before he could start work. The difficulty of the City Council was that they could not fix on any standard which the Electrical Trades Union had established. It was decided to hold a conference on the subject.

Burton-on-Trent.—At the recent inquiry into the Council's application for a loan for electric lighting extensions, a Mr. Wardle appeared in opposition, and passed certain criticisms on the system of supply and the management of the electricity undertaking. A lengthy report in reply has now been prepared and issued by the engineer and manager of the gas and electric light works (Mr. F. L. Ramsden), in which he deals with Mr. Wardle's comments *seriatim*. Mr. Ramsden first deals with the system of supply, and points out that in 1892, when it was decided to engage in electric lighting, their system was only adopted after careful consideration, and of the 14 firms who tendered for the supply of plant, 11 recommended the alternating current system, and two the continuous. The failures of the light had not been caused through any fault in the system but through the unsuitability of the insulating material of the high-tension mains. If it should be decided to establish electric tramways in Burton, they could, by the addition of suitable plant, supply the current as well and as cheaply as if they had the continuous-current system, and it would have been quite as necessary to put down special plant for tramways if they had originally adopted the latter system. Figures are quoted from the statistics given in *The Electrician* supplement sheet table (published in January) in order to refute Mr. Wardle's assertion that the alternating-current system is obsolete. The questions of the site of the station, machinery, mains, voltage, public lighting, financial results and extensions are also fully dealt with. Mr. Ramsden intimates that as soon as the additional plant has been fixed he will bring forward a "free" wiring scheme for the consideration of the Council. As to the objections to extensions, Mr. Ramsden has no difficulty in proving the futility of Mr. Wardle's statements. Our feeling in reading Mr. Ramsden's exhaustive report is that he has taken his critic too seriously, for not every self-constituted critic of electricity supply is thus honoured. Some of Mr. Wardle's statements were so utterly absurd as to carry their own refutation.

Caldas (Spain).—The local electric light company (a French concern) has taken advantage of a waterfall about one kilometre above this town to erect electricity works for lighting the towns of Padron, Carril, Villagarcia and Cambados. A contract has been entered into with the councils of these towns for public lighting, and an electric tram-line is to be constructed from Villagarcia to Cambados, a distance of 11 kilometres. It is anticipated that the lighting works will be opened early in June.

Cherbourg.—After an extensive trial of the Serpollet system of steam tramway traction, it has been decided to substitute electric tramcars on the overhead trolley system on the local lines. A telephone service is also to be installed.

Chesterfield.—The Council has received from an electricity supply company an offer to supply electricity in bulk at 2½d. per unit. The Council has appointed a special committee to consider the offer, and the committee thinks it could supply current at 1d. per unit. The question will be discussed at the next Council meeting.

Colchester.—The borough surveyor is engaged in the preparation of a report as to the advisability of providing additional electric lighting plant to meet the anticipated increased demand for current during the next two years.

Douglas (Isle of Man).—An electric lighting scheme, estimated to cost £12,000, has been decided upon by the Council. The Electric Light committee are to submit details of a project on the lines laid down by Prof. Fleming in his report to the Council.

Durham.—Like other local authorities, the Durham Council are endeavouring to induce the Board of Trade to allow the customary transfer clause to be inserted in their provisional order.

Eastbourne.—The borough surveyor has been authorised to prepare a scheme of electric tramways or light railways for this town.

Electrical Trades Union.—We are informed that it has been agreed to institute an apprenticeship system in connection with this union, and to admit electric traction employés as a separate section. It has been decided to increase the unemployed, strike and funeral benefits, and to add sick benefit. The fifth conference of the Union was held at Manchester on March 31 and April 1.

Electricity v. Gas.—At the annual meeting of the Scottish Gas Managers at Glasgow last week the president (Mr. William Young, of the Hamilton gas works) said that incandescent gas lighting still kept electricity in the background as an economical light, though, for the sake of being sole purveyors of light, Corporations who were at present owners of gas works would sooner or later have to supply the two illuminants or allow a company to come in and supply electricity. Mr. M'Gilchrist, of Dumbarton, did not know how it was that the producers of electric current were rushing away to the north when they had a much larger field before them in the south. He thought there was nothing to fear from electric light in the north. As a gas manager he would be very well pleased if an electric light company would go to Dumbarton and take up the lighting of the streets, because they could do that with more efficiency, and it was not a source of profit to a gas manager.

Electric Light at Buckingham Palace.—In the House of Commons on Monday, on the vote for works at the Royal palaces and Marlborough House, Mr. Caldwell asked when the electric light installation at Buckingham Palace, which was estimated to cost £11,000, and on which £3,500 had already been expended, was to be completed. The First Commissioner of Works (Mr. Akers-Douglas) explained that the amount which they were taking this year for the extension of the electric light in Buckingham Palace was an amount on account. A further sum would probably have to be expended before the service was complete. This matter was very carefully gone into by a committee two or three years ago from the point of view of safety from fire, and it was decided that, as far as possible, electric light should be used.

Farnworth (Lancs).—The Electrical committee is considering the terms of the Bolton Council to supply electricity "in bulk" in this district.

Fraudulent Bankruptcy.—At the Old Bailey (London) the Common Serjeant, on Wednesday, sentenced Claude Theodore James Vautin, electro-metallurgist, &c. (who pleaded guilty to an indictment charging him with having within four months before the presentation of a bankruptcy petition against him quitted England with a sum of £4,380 with intent to defraud his creditors) to six months' imprisonment without hard labour. Application was made that the money recovered should be handed over by prisoner's trustee in bankruptcy for the benefit of the creditors, and the Common Serjeant said no doubt the police would do this if formal application were made,

Fulham (London).—The Vestry have applied to the London County Council for a loan of £100,000 (to be repaid in 42 years) for electric lighting purposes.

Garston (Lancs.).—A hitch has occurred in the negotiations for the transfer of the Council's provisional order. The British Insulated Wire Co., to whom it is proposed to transfer the order, insist upon the Council taking the risk of the transfer being approved by the Board of Trade, a condition which the Council object to. On the completion of the transfer the company offer to pay all costs, but the Council require a depost of £200, and this the company are not willing to deposit.

Greenock.—Mr. John Young (manager of the Glasgow tramways) has been requested to prepare a report on the tramways in this town.

Harrogate.—The Council have taken up a loan of £15,750 from the Prudential Assurance Co. for electric lighting purposes.

Hereford.—An inquiry has been held here into the application of the Council to borrow £20,000 for electric lighting purposes. The town clerk (Mr. Carless) supported the application, and said that in 1823 the cost of public lighting by oil was £118. 2s. 6d. per annum, and in 1824 they entered into a contract for gas lighting

Digitized by Google

t a cost not exceeding £150 per annum. A number of tradesmen in the high town had private electric lighting installations, and the result was to create a demand for current for private lighting. A site for the generating station in Widemarsh-street had been acquired for £1,650. The continuous-current three-wire system of distribution would be adopted, and it was proposed to supply current at 220 volts. The estimated cost of the installation was £19,976.

Infirmary Lighting.—The Mill-road Infirmary of the West Derby Guardians is now lighted electrically. The plant has a capacity of 1,400 16 c.p. lamps. The boilers were supplied by Messrs. Fawcett, Preston and Co., and the steam engines by the Mirrlees, Watson and Yaryan Co., of Glasgow. A Chloride storage battery of 900 amp. hours' capacity has also been provided. The wiring work was executed by Messrs. Woodward and Craig, and the whole of the work has been carried out to the specification of Mr. Thomas L. Miller, of Liverpool.

Kilmainham (Dublin).—The Council has appointed a committee to consider and report upon the offer of the Municipal Industries Syndicate to supply electric current in the district. Mr. C. W. Sax attended on behalf of the syndicate at the last Council meeting to explain the syndicate's proposals.

Liverpool.—At the Council meeting, last week, Mr. Crean drew attention to a resolution of the Electric Power and Lighting committee, according to which, out of £84,000 standing to the credit of the committee, £9,000 was to be devoted to reserve and renewal, and £1,000 was to go in reduction of rates. He proposed the matter be referred for the reconsideration of the committee. Mr. John Henderson, who seconded, said that he fully expected that, in consequence of the reduction made in the price of current, to find a large diminution in the profits, but there was apparently an available balance of only £8,000, compared with £14,000 in the previous year. He found, however, that there was an extraordinary charge of £6,000 for the change of pressure supply. Notwithstanding the reduction in the price, the receipts were positively £4,000 or £5,000 more, and, instead of a net profit of £8,000, as it appeared in the account, it was really £13,000. Was not the electrical undertaking intended to relieve the ratepayers? If, however, profits were to be dealt with in this way, the ratepayers were not likely to get much benefit. In reply, the chairman of the committee (Mr. Petrie) stated that their policy was to bring electricity into closer competition with gas. In spending a large sum on their generating station they must get more consumers, and the only way to do that was by getting more people connected with their mains.

The City Council have sanctioned the revised scale of charges for electric current set out in our issue of 24th ult.

Lowestoft.—At an inquiry into the application of the Council to borrow £30,000 for electric lighting, the town clerk said that tenders had already been obtained (and provisionally accepted) for the supply and erection of plant and mains. The consulting electrical engineer (Mr. W. C. C. Hawtayne) submitted plans and specifications. The continuous-current three-wire system of distribution was proposed, and current would be supplied at a pressure not exceeding 500 volts. For street lighting it was intended to erect 32 arcs, and two 32 c.p. incandescents would be attached to each of the pillars for use after midnight. The aggregate capacity of the plant would be 225 kilowatts, in addition to which a 400 ampere hour accumulator battery would be provided. The estimate of capital outlay was as follows: Buildings, £4,000; generating plant (including boilers, engines, dynamos, accumulator, battery, switchboard, pipework, pumps, engine room overhead, travelling crane and station lighting), £7,973; underground mains for private lighting, £8,162; public lighting, £757; meters and house service connections, £2,000; engineering and legal expenses, £1,500; contingencies and unforeseen, £500; extension to Belle Vue Park, seven arc lamps and private distributing mains, £480; also Grand Hotel, Kirkley, 13 arcs for private distributing mains, £2,800; total, £28,172. There was no opposition.

Manchester.—As the Corporation will shortly be called upon to supply electric current for traction purposes, the question of the provision of separate generating plant for the tramways, as recommended by Mr. Parshall at Glasgow, is exciting some interest in civic circles. The city electrical engineer (Mr. C. H. Wordingham), however, is of opinion that, as the plant employed at Manchester is capable of supplying current for lighting and traction, it is not necessary to provide special traction plant. The combination of the lighting and traction undertakings rendered it possible to have a larger generating station with less cost for attendance per unit generated; it reduced the losses from idle plant, &c.; and the cost of supervision was minimised. Under a dual system the repairing staff would require to be duplicated. Combination would also effect a reduction in the amount of spare plant required, and other economies could also be effected. The position was debated at some length by the Tramways committee on Tuesday, when it was decided to appoint a special committee to confer with the Electricity committee in regard to the generation of electric energy for the tramways, and the committee were empowered to obtain such expert and other advice and assistance as they might deem necessary.

Contrary to the recommendation of their Telephone committee, not to send a deputation to the Chancellor of the Exchequer in support of the application of the Mutual Telephone Co. for a telephone licence for Manchester, the City Council have elected Aldermen Southern and Copeland to attend and support the company's application.

Newcastle-upon-Tyne.—In February last, the borough engineer (Mr. W. G. Laws) was instructed to report (along with Prof. Alex. B. W. Kennedy) as to "whether in the streets in the centre of the city some system other than overhead traction is practicable to be worked in conjunction with the overhead system in the other streets." Before the promotion of the last Tramways Bill, Mr. Laws had reported in favour of cabling the tramways, but the new Tramways committee obtained two other reports—one from the late Dr. John Hopkinson, who strongly recommended the overhead trolley; but as there was considerable objection to the use of this system in the centre of the city it was thought advisable to obtain further information on the matter. Owing to Prof. Kennedy being compelled to visit the United States on behalf of the London County Council, he has not yet been able to visit Newcastle in order to prepare his report. In the report under notice, Mr. Laws strongly objects to the overhead system on æsthetic grounds. So far, he says, no stress has been laid on the æsthetic objection to the overhead wires as an eyesore that would seriously damage the appearance of a fine old town. There was still hope that those whose sense of the fitness of things led them successfully to resist the proposed invasion of the telegraph, telephone and electric light companies (who would cheerfully have spun their unsightly web over the town to save their own pockets) would yet hesitate to do themselves what they rightly refused permission to others to do. After expressing himself in the strongest possible language against the trolley for traction, Mr. Laws says the lighting of the streets should not be run from the same circuit as the trams, or the consequences of temporary failure would be intensified, and "just when the trams were left helpless in the streets, the light that should guide other vehicles would be wanting." He is of opinion that the suggested æsthetic sacrifice was unnecessary, and asks, "Is there any system by which electric traction is possible without the poles and wires?" There were the underground conduit, the surface contact, and the self-contained automotor car; but of each of these there were several modifications, all of which had been tried, and several of them successfully. Mr. Laws refers to Siemens and Halske's conduit system as being in successful operation in Buda-Pesth and other places, while Love's conduit had been installed in Washington and New York. The Simplex had been laid down experimentally at Prescot, and to his mind it was the most promising of the open conduits, and well worth considering. He understood that the first cost of this system was but little in excess of the trolley. The culvert or conduit was so shallow (only 17in. below rail level), that it could be constructed within the thickness of an ordinary first-class paved road, and so avoid the extensive alterations to gas or water pipes that have proved so costly with the deeper conduits. The Love system had a separate conductor for the return current, thus avoiding danger of electrolysis to neighbouring pipes. Of all the conduit systems, these two seemed to him to promise best, and, subject to the technical point of whether they would work in the English climate as well as the underground system did in Buda-Pesth, and was said to do in New York, they appeared to him to be mechanically right. Mr. Laws next deals with the cost of working. They had no information as regarded the Simplex, and only one report as to the Love system, which was as under:—

Operating Expenses per Car Mile for –

	Chicago, 1895.	Chicago, 1898.	New York, 1898.
Cable	5d.	... 5¼d.	... 8¼d.
Horse	12⅜d.	... 13d.	... 9d.
Electric ...	8½d. (trolley).	... 6¾d. (trolley).	... 5½d. (conduit).

If the New York figures were reliable, they showed that underground electric is run at even less than overhead. This required some explanation. When, in 1893, the favourable results at Buda-Pesth were announced, he expressed his doubts as to whether these results would be realised in the English climate. He still held those doubts, though they were to some extent shaken by the New York results. But, if in America conduit could rival trolley, there was no apparent reason why it should not do so in England. Mr. Laws declares that the objections to the surface contact system are fatal, and as to automotive or accumulator systems he observes that if financially possible there was no other system that could offer such advantages. There was no more interference with the streets than in the case of a horse tramway, no underground complication, no overhead abominations. The chief objection to the accumulator system was the great weight of the accumulators, increasing the dead weight to be hauled (always large in electric

Digitized by Google

cars) by about two tons. The experiments hitherto made in England had not been financially successful. In Birmingham they resulted in a loss of 2d. per car mile. The whole question hinged on the invention of a suitable storage battery, lighter, more effective, and more durable than anything hitherto tried. That this want would be supplied the rapid progress of electric knowledge led one to believe. That it was being gradually improved one saw. During his visit to Copenhagen in 1897 he found a short automotive line in full work running from Kongens Nytorv to the Jagt Vej, a distance of something over a mile and a half. The fare for the run was ½d. He was unable to ascertain anything about costs of working, being told that they were not made public yet, but came to the conclusion that if with such fares the line could even exist, the system was by no means out of the running. The charging of the batteries was done in the public square of Kongens Nytorv in the heart of the town, from small pillars, less in size than an ordinary hydrant, with a small flexible hose or cable attached. The car, as soon as it reached the terminus, was shunted on to a short siding, the plug of one of these cables stuck into a small hole in the car side, and there it waited its turn for service; a charged car being run out of the forward end of the siding for the next journey. There was no vapour observable, and the cars were even more manageable and handy than the trolley car. Mechanically, the whole of Newcastle could be worked on such a system, from one charging station. The only doubtful point was that of working cost. Mr. Laws thinks that if the council adopt the conduit in the centre of the town, it would be possible to work it in conjunction with the trolley in the outskirts. As to the question of within what radius the conduit or other poleless system should be adopted, he thought that the wider such radius was the better. To sum up, and put my opinion on record (says Mr. Laws) it is this:—Unless expert opinion condemns the conduit as unworkable in this climate, it should be adopted as against the trolley, certainly in the major part of the town. If the council comes to that opinion, the Simplex, or some modification of it, is the most promising, and, failing that, the Love. But again, unless expert opinion condemns the accumulator, as worked at Copenhagen, and it proved to be financially impossible, that is preferable to either conduit or trolley.

The poll of property owners and ratepayers on the proposal to construct an electric tramway in the town has resulted in a majority of 1,207 votes in favour of the Council's Bill—12,633 for, and 11,416 against.

New Pacific Cable Scheme.—The *Standard* of Tuesday contained a communication from its Berlin correspondent giving some particulars of the project of the New York Pacific Cable Co. for laying a submarine telegraph cable between the United States and the Philippines, a distance of 11,000 miles. According to the particulars published, the cable is to touch at Hawaii and the Carolines, thence to the Southern Ladrones and on to Manila. The weight of the cable is to be 28 tons per mile, and a one-sixteenth slack is to be allowed. According to the particulars given, the cost of the cable is to be "$1,000 per mile." The starting-point is to be Monterey, California, the other end being the Island of Luzon. Two years are to be allowed for the manufacture and laying of the cable. The longest section of the proposed cable will be from San Francisco to Hawaii—2,098 miles. Those of our readers interested in Pacific cable schemes will, doubtless, turn to the columns of our contemporary for further particulars.

Perth.—The Council have unanimously decided not to part with their provisional order, and steps are to be taken to establish municipal electricity supply.

Ramsbottom.—The Lighting committee have been authorised to take into consideration the question of taking immediate steps for providing a system of electricity supply.

Shrewsbury.—Four additional arc lamps are to be erected by the Electric Lighting committee and various extensions of the plant and mains, which have been recommended by the borough electrical engineer (Mr. C. M. Johnston), are to be carried out at an estimated expenditure of £4,139.

Southport.—In a report to the Electric Lighting committee the borough electrical engineer (Mr. C. D. Taite) estimates that a sum of £55,000 will have to be spent in providing additional electric lighting and traction plant during the next two years, the greater part of this outlay being due to the proposal of the Council to establish a system of electric tramways. The electricity undertaking is making steady progress. The number of consumers at the end of March was 520, and the equivalent number of 8 c.p. lamps connected was 35,489. The matter was discussed at the Council meeting on Tuesday, when Mr. Taite's proposals were submitted by the committee for the Council's approval. After discussion, however, it was decided to consult with the Finance and Tramways committees before finally deciding the matter.

Stretford.—The Council have applied to the Board of Trade for a two years' extension of the period for complying with their provisional order, obtained in 1897.

Telephone Trunk Line Extensions.—The telephone trunk line system of the country has been extended to Newquay, Cornwall.

The Electrical Industry in Germany.—Seven of the most important electrical firms in Germany have issued a circular to the effect that, in consequence of the higher prices of raw materials, they have decided to increase by 5 per cent. the prices of various electric products. The circular is signed by the Siemens and Halske, Aktiengesellschaft, the Allgemeine Elektricitäts Gesellschaft, the Schuckert Company, the Helios Company, O. L. Kummer and Co., the Lahmeyer Company, Felten and Guilleaume, and some smaller firms.

Tin v. Copper.—A financial contemporary, in referring to the important rise in the price of tin, ascribes this to a development in the use of this metal in substitution for copper in electric installation work.

Train Lighting.—The Board of Directors of the South Indian Railway have considered a report submitted by their agent on various systems of lighting trains, and has approved of the "Stone" system, which was described in *The Electrician*, Vol. XXXIX., p. 808, and has called for an estimate of its cost with a view to its adoption.

Tramways in Spain.—Messrs. Dick, Kerr and Co. have sent us a pamphlet reprint of articles descriptive of the Barcelona and Madrid electric tramways. The illustrations, photographic views, and sectional drawings are excellent.

Wallasey.—An inquiry was held here on Wednesday into the application of the District Council to borrow £10,000 for electric lighting purposes. The present loan was the balance of the expenditure proposed (£27,540) to be incurred in 1897, and was made up of £5,000 for a 300 kilowatt alternator, £1,500 for boilers, £1,200 for cable, £1,000 for service meters, and other minor items. The engineer (Mr. J. H. Crowther) stated that he did not think any portion of the amount would be needed before next year, but the district was rapidly increasing in population, and the demand for current was keeping pace with that increase. The proposed extension would be sufficient to meet their requirements for three years at the present rate of increase. There was no opposition.

Walsall.—In order to encourage the increased consumption of electric current for lighting, the Council have decided to allow an additional discount of 10 per cent. where the yearly consumption is between 10,000 and 15,000 units, and a discount of 12½ per cent. when more than 15,000 units are used.

Will.—The will of the late Mr. William George Forster, for many years a superintendent of the Eastern Telegraph Co., was proved on March 8, by Mrs. Jessie Forster, the widow and sole executrix. The value of the estate is £3,597 16s. 2d.

Worcester.—The Streets committee are to obtain expert opinion as to the advisability of taking over the local tramways, and as to the probable cost of converting the lines to electric traction.

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. Chapman and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application an asterisk is affixed.*

February 28, 1899.

4,360. E. Vedovelli and C. Priestley. London. Improvements in or relating to apparatus for use in electric traction on the conduit system.

4,370. P. Stevenson. Glasgow. A rise and fall pendant or electrolier for electric light.

4,409. A. Heiny. London. Automatic telephone exchange system.

4,415. H. H. Lake. London. Improvements in apparatus for use in electro-plating. (R. H. Boissier, United States.)

4,416. B. L. Lamme. London. Improvements in direct current systems of electrical distribution. (Date applied for under Patents, &c., Act, 1883, Sec. 103, August 4, 1898, being date of application in United States.)

4,417. F. Jones and F. A. Pocklington. Liverpool. Improvements in or relating to conduits for electric conductors.

March 1, 1899.

4,455. R. Riley, T. Winstanley and S. Riley. Manchester. Improvements in and appertaining to electric street tramways.

4,486. J. E. Kelly. London. Improvements in electric signals and alarms.

4,496. G. Bowron. London. Improvements in or relating to electrical contact-breakers.

4,498. G. Blank and H. M. Salmony and Co. (Limited). London. Improvements in and relating to telephonic apparatus.
4 512. W. J. Murphy and G. Draper. London. Improvements in and relating to perforators for use in connection with automatic telegraph transmitters.
4,528. A. R. Gould. Manchester, Improvements in electric bells for cycles and other vehicles.

March 2, 1899.

4,595. R. H. Lendrum. Huddersfield. Improvements in apparatus for working tramways by electric power.
4,598. J. Sturgeon. Leeds. Protecting the overhead wires of electric tramways and construction of trolley or current collector adapted thereto.
4,605. A. D. Stevenson and A. V. Gipkins. London. Improvements in electric motor controllers.
4,632. C. J. Reed. London. Improvements relating to the operation of electric motors at different speeds.
4,633. C. J. Reed. London. Improvement in method of and means for operating electric motors. (Date applied for under Patents, &c., Act, 1883, Sec. 103, August 17, 1898, being date of application.)

March 3, 1899.

4,683. H. F. Parshall. London. Improvements in automatic switches for alternating electric-current circuits.
4,684. H. F. Parshall. London. A method of and apparatus for regulating the voltage of electric currents.
4,699. H. F. Clayton. London. An improved ceiling rose for electric lights and the like.*
4,705. A. M. Stansfield. Liverpool. Improvements in connecting boxes or fittings for use with electric conductors.
4,727. A. M. Taylor. London. Improvements in and connected with electric tramway and railway conduits.

March 4, 1899

4,774. F. W. Heaton and H. Smith. Salford. An improved electrical cut out or fuse.
4,778. P. J. Wilkinson and C. P. L. Titherley. Liverpool. An improved electric therapeutic apparatus.
4,783. W. J. Davy. London. Improvements in or connected with electric arc lamps.
4,801. J. H. Holmes and F. Broadbent. London. Improvements in and connected with resistance switches for electric circuits.
4,821. A. G. Brookes. London. Improvements in and relating to motor-suspension for electrically driven vehicles. (T. Stort, Germany.)
4,822. A. G. Brookes. London. Improvements in and relating to motor-suspension for electric auto-motor vehicles. (T. Stort, Germany.)
4,838. C. H. Cole. London. Improvements in portable electric primary batteries.

March 6, 1899.

4,845. L. Zahn. Berlin. Improvements in apparatus for registering the supply of electricity.
4,863. W. Cook and W. Kinzett. Redditch. An improved indestructible insulator for electric engineering purposes.
4,865. B. J. Round, B. J. Round and A. Round, Birmingham. An improved electro-gilding process and apparatus to be used in connection therewith,
4,878. G. Wilkinson. London. An improved case for electrical transformer connections, also applicable to street electric light standards.*
4,879. A. S. Frazer and G. A. Smith. London. A new or improved electric battery cell and elements therefor.
4,931. W. L. Wise. London. Means for generating and impressing semi-cycles of electromotive force on electric circuits for telegraphic and other purposes. (A. C. Crehore and G. O. Squier, United States.)

March 7, 1899.

4,941. J. Eck. London. Improvements in the governing of electric motors.
4,954. J. Butcher. Wolverhampton Improvements in electric clocks.*
5,010. E. F. Moy and P. H. Bastie. London. Improvements in or relating to electrical incandescent lamps.
5,030. O. Imray. London. Improvements in control apparatus for electric hoists and elevators. (A. E. Maccoun. United States.)*
5,041. W. B. Sayers and Mavor and Coulson (Limited). London. Improvements in dynamo-electric machines.
5,042. W. B. Sayers and Mavor and Coulson (Limited). London. Improvements in dynamo-electric machines.

March 8, 1899.

5,096. H. F. Purser. London. An electric opera, field, or marine glass.
5,099. E. Goller. London. Storage plates for accumulators and process for the manufacture of same.
5,100. V. B. D. Cooper and E. Ridley. London. Improvements in and relating to methods for charging accumulators.*
5,104. F. Braun. London. Reinforcement of electrical waves and avoidance of loss by straying reflection, &c., by means of a condenser.
5,111. G. Schünemann and O. Rieder. London. A new or improved electrically-operated gas-tap and apparatus for lighting at a distance.*

March 9, 1899.

5,130. J. G. Statter. London. Improvements in electrical time switches.
5,151. F. B. Cox. Liverpool. An improved envelope for electrical conductors.
5,190. J. M. Overshiner. London. Improvements in telephone switch boards.*
5,191. C. Curwen. London. Improvements in lighting electric lamps.
5,197. H. W. Bowden and W. J. Allbright. London. Improvements in electrical power station switches.
5,199. T. J. Holland and A. P. Laurie. London. Improvements in electrolytic decomposing apparatus.
5,200. T. J. Holland and A. P. Laurie. London. Improvements in the manufacture of porous diaphragms for electrolytic apparatus.
5,211. A. H. Miller. London. Improvements in electric incandescent lamps.
5,217. J. Burke. London. Improved construction of commutators for dynamos and electromotors.*
5,229. The British Thomson-Houston Co. (Limited). London. Improvements in apparatus for making and breaking high potential electric circuits. (E. M. Hewlett, United States.)*

SPECIFICATIONS PUBLISHED.

Note.—All Specifications can now be obtained at the uniform price of 8d. each.

1897

26,118. Benjamin. Conduit and aërial electro-locomotor primarily fo laying or drawing in electric mains or other cables for any service

27,128. VARICAS and VARICAS. Etheric steering apparatus for controlling from a distance the steering gear of ships, torpedoes and other floating bodies electrically.
27,531. BROOKES. Berliner electro-mechanische Werkstätten (Gesellschaft mit beschränkter Haftung.) Graphophones.
27,593. BRITISH THOMSON-HOUSTON CO., LIMITED (Case). Systems of train control for electrically-propelled vehicles.
27,613. HOWARD. Electric fuse holders.

COMPANIES' MEETINGS AND REPORTS.

Indo-European Telegraph Co. (Limited).

The Directors, in their report for 1898, refer to the death of their late colleague, Consul H. H. Meier, of Bremen, who died in November, and who had been connected with the Company since its commencement. The vacancy will be filled by the appointment of his son, Dr. H. H. Meier. The Company's revenue from all sources for 1898 amounted to £134,642. 12s. 11d., compared with £130,347. 3s. 5d. for 1897. The expenses were £74,346. 0s. 5d., against £69,378. 13s. 5d. for 1897. Deducting the above expenses, taking credit for £9,703. 4s. 1d. from 1897, and debiting income tax, there remains the sum of £67,202. 0s. 9d. From this £15,000 has been placed to reserve, and deducting this sum, together with £10,625 interim dividend, there remains a balance of £41,577. 0s. 9d. The Directors propose to declare a dividend for the six months ended Dec. 31 of 17s. 6d. per share, making (with dividend already paid) 6 per cent. and a bonus of 20s. per share, both free of tax, making 10 per cent. for the year, carrying forward £9,702. 0s. 9d.

The lines of the Company continue to work satisfactorily, and the extension of the Wheatstone automatic apparatus, which in part accounts for the extra outlay on expenses and charges for maintenance, has proved successful; the system has also now been established from Emden to Teheran. An additional wire has been erected from Warsaw to Odessa.

The transfer books are closed from 13th to 27th inst., inclusive.

EDWARDS AIR PUMP SYNDICATE (LIMITED).—The first annual report of the directors of the company for the period to Dec. 31 last states that a net profit has been made of £128. 8s. 11d. Additional patent rights for improvements in steam engine air pumps have been obtained in a number of leading European countries. The report states that the syndicate's pump is steadily gaining in popularity with superintending engineers and with consulting engineers, who are more particularly identified with stationary engines for electric light and power plant. The Edwards pump has been specified for some of the largest corporation electrical installations in the Kingdom.

ELMORE'S GERMAN AND AUSTRO-HUNGARIAN METAL CO. (LTD.).—The directors' report for 1893 states that beyond the increase of the debenture stock from £44,994 to £60,000 and the increase of the loan to the Metall Company to £53,608 there is little alteration in the figures from those of 1897. £4,153 was paid last year to the debenture holders by way of interest. The directors were unable to carry through the negotiations for the sale of a license in Austria-Hungary, and they are of opinion that it is not now in the interest of the company to sell the patents or to grant a licence. The Metall Co.'s accounts show a considerable increase compared with the previous year. The directors have purchased an additional engine and boiler, which greatly increases the steam reserve. The weight of goods of the company's own production sold during the period showed an increase of over 90 per cent. compared with last year, while the output has averaged over 19 tons per week. The directors of the Metall Co. believe it would be in the interest of the company not to pay a dividend, but in view of the long period taken to reach the dividend-earning stage they declared a dividend. The amount to be received by the Austrian company from the Metall company is £7,500, from which has to be deducted the charges (£3,235) of the past year. From the balance the directors recommend the payment of an interim dividend of 7½ per cent., or 3s. per share, free of tax, to the Preference shareholders. The one-tenth of the net profit due to the Ordinary shareholders, being too small for division, will be carried forward.

NEW COMPANIES, STATUTORY RETURNS, &c.

BEDFORD MOTOR-CAR SYNDICATE (LIMITED).—This syndicate was registered on April 6, with a capital of £2,000, in £5 shares, to carry on in Bedford or elsewhere the business of tramway, railway, omnibus, motor-car and van proprietors, dynamo and locomotive builders, &c.

COTSWORTH ARC LAMP AND ELECTRIC LIGHTING SYNDICATE (LIMITED).—This company was registered on April 6, with a capital of £25,000, in £1 shares, to acquire certain British and German patent rights granted to Mr. Haldane G. Cotsworth, for improvements in connection with the manufacture of electric arc lamps, together with the benefit of an 100-hour enclosed arc lamp, a 40-hour double carbon lamp, and a photographic printing lamp, and to carry on the bussness of electricians, electrical and mechanical engineers, electric lamp and apparatus manufacturers, suppliers of electricity, &c. The first subscribers are: Haldane G. Cotsworth, electrical engineer (10 shares), Alfred Haynes (5 shares), G. A. Wright (5 shares), C. G. L. Cator (10 shares), A. Gascoine (5 shares), Arthur Mackenzie (1 share), and P. C. J. Macphee (1 share).

ELECTRIC TIMBER-SEASONING AND PRESERVATION CO. (LIMITED).—This company was registered on April 10, with a capital of £150,000, in £1 shares (of which 60,000 are Preference), to enter into agreements with the Founders' Syndicate (Limited), and with Mr. Walter C. Johnson, to acquire and work certain patents, to handle, store, import, export, prepare, preserve, season, sell and deal in wood, timber and fibrous matters of all kinds, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and electrical apparatus manufacturers. The first subscribers are:—F. C. Cross, H. Baillie Weaver, C. Brooks, F. D. Head, L. Weaver, E. Choat and G. W. Brown.

FERROLITE ELECTRIC SYNDICATE (LIMITED).—This company was registered on April 5, with a capital of £30,000, divided into 8,000 "A" and 22,000 "B" shares of £1 each, to acquire provisional patents Nos. 22,070, 23,306 and 23,307 (1898) granted to Mr. C. Levetus for improvements in and relating to galvanic and other batteries, and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity, and manufacturers of and dealers in electrical apparatus. The first subscribers are: E. L. Levetus, A. L. Collins, V. Page, H. C. Sawyer, J. M. Bell, E. J. White, and G. L. Laming. The first Directors are Hyman Levetus and Edward L. Levetus.

LONGFORD WIRE COMPANY (LIMITED).—This company was registered on April 6, with a capital of £100,000, in £1 shares, to acquire the business of the Longford Wire, Iron and Steel Company (Limited), and to carry on the business of wire drawers and weavers, mechanical and electrical engineers, machinists, &c. The first directors are:—John Geddes, J.P., Charles J. Holmes, J.P., John L. Tunstall, Richard T. Fairclough, J.P., and James F. Dutton.

NEILD'S SLEEVE ELECTRIC JOINT SYNDICATE (LIMITED).—This company was registered on April 4 with a capital of £5,000, in £1 shares, to enter into an agreement with Harry W. Neild, to acquire certain British and foreign patents and rights, and to carry on the business of electricians, mechanical engineers, and manufacturers of and dealers in electrical apparatus, telegraph and telephone instruments, cables, wires, &c. The first subscribers are:—J. Myerson, W. H. Harton, H. W. Neild (engineer), C. C. Christopher, F. C. Pallett, C. H. L. Alder, and H. W. Allason.

POOLE AND DISTRICT ELECTRIC TRACTION CO. (LIMITED).—This company was registered on April 5, with a capital of £100,000, in £10 shares, to enter into an agreement with the British Electric Traction Co. (Limited), the Bournemouth, Poole and District Light Railways (Electric) Co. (Limited), and Mr. W. Murphy, and to carry on the business of electricians, electrical and mechanical engineers and contractors, suppliers of electricity, manufacturers of and dealers in electrical apparatus, tramway and light railway proprietors, and carriers of passengers and goods. The first subscribers are: Emile Garcke, George Stevens, C. H. Dade, S. Sellon, Ch. H. Gadsby, W. M. Murphy, and J. Lewis.

YOUNG AND MARTEN (LIMITED).—This company was registered on April 5, with a capital of £275,000, in £1 shares (150,000 Six per Cent. Cumulative Preference), to acquire the business carried on under the style of Young and Marten, and to carry on the business of iron and brass founders, metal workers, mechanical and electrical engineers, machinists, &c.

ANGLO-AMERICAN TELEGRAPH CO. (LIMITED).—The annual return to Feb. 17 has been filed. The capital is £7,000,000 stock, all of which is fully paid up.

CITY OF LONDON ELECTRIC LIGHTING CO. (LIMITED).—The annual return to March 15 has been filed. The nominal capital is £1,200,000, in £10 shares (of which 400,000 are Preference). 60,000 Ordinary and 40,000 Preference shares have been taken up, and the full amount has been called.

NATIONAL TELEPHONE CO. (LIMITED).—The annual return to March 3 has been filed. The capital is £4,000,000, divided into 15,000 First Preference shares of £10 each, 15,000 Second Preference shares of £10 each 250,000 Third Preference shares of £5 each, and 490,000 Ordinary shares of £5 each. All of these have been taken up, and 28,284 of the Third Preference and 44,413 Ordinary have been issued as fully paid. The full amount has been called on the remainder.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY CO. (LIMITED).—The annual return to March 7 has been filed. The capital is £100,000, in £5 shares, of which 12,370 have been taken up; 412 have been issued as fully paid, and the full amount has been called on 8,958, while £2. 10s. per share has been called on 3,000.

NORTHWICH ELECTRIC SUPPLY CO. (LIMITED).—According to the annual return to March 13 the capital is 25,000, in £5 shares, of which 3,000 have been taken up. The full amount has been called.

Digitized by Google

NOTTING HILL ELECTRIC LIGHTING CO. (LIMITED).—The annual return to March 15 has been filed. The capital is £100,000, divided into 6,452 Ordinary, 550 Founders' and 2,998 Preference shares of £10 each. All of these have been taken up, and the full amount has been called and received.

TELEGRAPH CONSTRUCTION AND MAINTENANCE CO. (LIMITED).—The annual return to March 14 has been filed. The whole capital of £448,200, in £12 shares, has been taken up and paid for in full.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (since Feb. 2, 1899). Price of silver 27 7/16d. per oz. (April 13). Consols (2¾ per cent.) 110¾—110⅞ for money, 110 7/16—110 9/16 for account; 2½ per cent. 103—103¼ (April 13), Stock Exchange Settling Days: Consols, May 4; Stocks and Shares Continuation Day, April 25; Ticket Day, April 26; Pay Day, April 27; Mining Share Carry over Days, April 24 and May 9.

CUBA SUBMARINE TELEGRAPH CO. (LIMITED).—The directors recommend a dividend at the rate of 6 per cent. per annum and a bonus of 2s. per share on the Ordinary shares, both tax free, for the half-year ended Dec. 31,

EASTERN EXTENSION, AUSTRALASIA AND CHINA TELEGRAPH CO. (LIMITED).—A dividend for the quarter ended Dec. 31 last of 2s. 6d. per share, together with a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1898, has been declared, payable on 27th inst. The share register will be closed from 19th to 26th inst. inclusive.

A list of 473 Five per Cent. Australian Government subsidy debentures in this company will be found set out in an advertisement on another page. These debentures have been drawn for payment at par, on July 1, by Messrs. Barclay and Co., 54, Lombard-street, London, E.C., and interest will cease on that date.

GLOBE TELEGRAPH AND TRUST CO. (LIMITED).—The financial papers announce that the directors of this company have agreed to recommend an interim dividend of 2s. 6d. per share on the Ordinary shares.

MUNICIPAL ISSUES.—During the week the Portsmouth Corporation invited applications for £188,000 £2. 15s. per cent. redeemable stock at a minimum price of 97. Amongst the securities are the municipal electricity works. The Huddersfield Town Council have decided to create £600,000 Corporation stock for the redemption of existing tramway loans, for electric lighting and other purposes.

METROPOLITAN ELECTRIC SUPPLY CO. (LIMITED).—Mr. James Carr Saunders has been elected a director of this company.

ORIENTAL TELEPHONE AND ELECTRIC CO. (LIMITED).—Subject to final audit, the directors have declared a further dividend of 8d. per share, free of tax, making, together with the interim dividend paid in October last, 5 per cent. for the year ended Dec. 31 last. The register of transfers will be closed from the 15th to the 26th inst., inclusive.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT CO. (LIMITED).—The amount of electricity sold by this company during the quarter ended March 25 is returned at 1,161,987 units, estimated to produce £21,061, against 1,016,642 units, which produced £20,036, for the corresponding period of last year. A further reduction of charges was made from January 1, 1899.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed Wednesday, the 19th inst., a special settling day in £100,000 Four Per Cent. First Mortgage Debenture stock of *Davey, Paxman and Co. (Limited)*, and has also ordered the stock to be quoted in the Official List.

NOTES.

SHAREHOLDERS in submarine cable companies will be very foolish if they do not take warning by what befell the proprietors in gas undertakings a few years ago. There was a scare, based on the premature belief that electricity would oust the older illuminant; yet gas stocks were never higher than they are to-day. It may be remembered, also, that when Lord KELVIN brought over from France his "million of foot-pounds" of energy, the effect which the Faure accumulator would have on the electrical industry was vastly overestimated. That a decided decrease in the market value of shares in cable companies is attributable to Mr. MARCONI's recent successful experiments may appear ridiculous to those who understand the subject, but it is, nevertheless, fact.

IT would be unwise to say that wireless telegraphy will never be made available for long-distance ocean work, but it may be confidently asserted that the advance in this branch of communication, like all other human progress, must be tentative and very gradual; and that the difficulties to be overcome are numerous and great. On the other hand, many of the cable companies are in the strongest possible position, with very large reserves; and, even if it prove feasible to work without wires, say, between London and Paris—all such messages being carried by the British and French Governments and not by the companies—it would be a thousand pities if timid shareholders were to sacrifice their property now, only to see it, after a year or even a few months, approximate to its former market level. The investing public speak of a "fall" on the Stock Exchange, but they ought to remember that it is, in this case, only themselves who, by panic selling, can largely depreciate for a time the value of their property.

OUR earnest advice, therefore, to holders is to continue to believe that the securities of well established cable enterprises are thoroughly sound investments, and to "sit on" what they have. If they do not, they will only have to blame their credulous acceptance of ill-advised and premature forecasts made by men who possess neither scientific nor practical knowledge of the subject. Those, on the other hand, who have worked with Hertzian wave and other systems of wireless telegraphy—men like Mr. MARCONI, Mr. PREECE, Prof. LODGE and Dr. FLEMING—best know the difficulties, some perhaps in their nature insuperable, which would have to be overcome, and are strongest in the belief that the field for this kind of communication is not that of long-distance telegraphy for which wires will always be found to be most suitable.

THE case for a Pacific cable, and for "all-British" cables generally, was laid before Parliament by Mr. WEBSTER in a temperately worded speech last week. Its one great fault was that it took no account of the manifold objections which have been pointed out, over and over again, as regards these schemes, by practical experts. It is possible that even without subsidies the Pacific cable will be laid, if capital can be tempted to support such hazardous adventure. Up to now, the serious risks, and the certainty that one cable alone would be worse than useless, have combined to favour the longer route with, however, shorter lengths of cables, in preference to the shorter one which would require longer stretches of cable, across the Pacific. Such is the case, so far as concerns the American and Australasian continents. As to the European countries it matters little whether their cablegrams travel westwards or eastwards; but it matters greatly that the route shall be abundantly provided with lines of communication—an advantage which the Eastern cables have always afforded, but which can never be obtained from the Western hemisphere. Mr. WEBSTER's suggestion, that the State should begin cable-laying on its own account in all parts of the British Empire, is based on the erroneous idea that cables landed where the home flag flies are safer than when they touch foreign soil. His financial conceptions are still more speculative. On this aspect of the question we commend to his attention Mr. F. E. BAINES's letter in *The Times* of the 11th inst.

Digitized by Google

What it says as to the telephone business and State competition is equally true of cable business. These considerations will have due weight with the British government; and it does not surprise us that Mr. CHAMBERLAIN has not yet come to any understanding on the subject with the Canadian and Australian governments.

RUMOURS have been published concerning the so-called negotiations between the Streets Committee of the City of London Corporation and the City of London Electric Lighting Co. The statements made are only partially accurate. In the course of an informal conversation between officials of the Company and members of the Streets Committee at the recent Board of Trade inquiry, it was pointed out by the former that the Company had always endeavoured to approach the Committee with a view of adjusting in an amicable manner the points of difference which had arisen from time to time, but that the Committee had invariably held aloof from these approaches. We understand that on the same occasion a suggestion was made for a conference between representatives of the two parties, and that the Company have accordingly approached the Streets Committee with a view to talking matters over. A formal acknowledgment agreeing to this proposal has been received by the Company. It may be mentioned that Mr. A. C. Morton, who has taken a prominent part in the opposition to the City of London Company, was present during the informal conversation referred to above.

ONE of the American inventions which we have no desire to see introduced on this side of the Atlantic is the accomplishment of wire-stealing. In the United States this is usually practised on lengths of trolley or other overhead wire, which is cut from the poles, and for which it seems the thieves have found a ready market. In fact, so remunerative has this business become that some of the gentlemen who carry it on have been known to have first gone through an apprenticeship as wiremen, in order to apply their acquired knowledge subsequently—with the sign changed. Some, indeed, have acquired such dexterity as to be able to cut down live trolley wire and safely convey it away. From a case reported in another column, it appears that wire-stealing has commenced in this country in a much less sportsmanlike manner. In no circumstances can one have sympathy with men who enter an electric light company's premises with a false key and cart off new wire in order to sell it for old metal, and we are glad that the sentences imposed on them have been exemplary. It is to be hoped that electrical engineers will profit by the lesson and see that better care is taken of their stores. Money invested in a good lock is cheap burglar insurance.

A RECENT article in the *Lancet* points to the possibility of disease being carried from one house to another by infected air passing through the pipes leading in electric light wires. Our contemporary recommends that the ends of these pipes should be plugged. Of course they should.

A Correction.—In our notes on wireless telegraphy, last week, we stated that Capt. Baden-Powell had, in a letter to *The Times*, somewhat thoughtlessly appealed to the Post Office not to assert its monopoly against this method of telegraphing. This was an error, the passage referred to having occurred in Major Flood Page's letter, and not in that of Capt. Baden-Powell, to whom we apologise for the mistake.

Cable Interruptions.	Date of Interruption.
Cayenne—Pinheiro	Mar. 10, 1899
Maranhan—Para.....	April 10, 1899

Proposed German Submarine Cable.—The Convention recently concluded between the German Empire and Roumania is said to provide, among other things, for the construction of a telegraph line and submarine cable from Berlin to Constantinople, *via* Galicia, Bucharest and Constanza.

A New Source of Platinum.—According to a consular report, quoted in the *Electrical World* of New York, a black sand, rich in platinum, has been found in the Yukon. An analysis, it is said, showed that, taking the price of platinum at $8 per ounce, one ton of sand contains $768 worth of platinum, besides $102 worth of gold.

The Proposed Canado-Australian Cable.—A Reuter's telegram announces that the Hon. William Mulock, the Dominion Postmaster-General, has given notice of a resolution authorising the Canadian Government to enter into an agreement with the United Kingdom and the Australasian possessions to construct, lay and operate a cable between Canada and Australia on certain conditions.

The Proposed Memorial to Clerk Maxwell.—We are asked to state that the subscription list for the proposed memorial to the late Prof. James Clerk Maxwell in the parish church of Corsock, referred to in our issue of October 14th last, is still open. Subscriptions limited to half a guinea will be gladly received and acknowledged by the Rev. George Sturrock, The Manse, Corsock, near Dalbeattie, N.B.

A Large Electric Fan.—What will be one of the largest ventilating fans in the world has been ordered for the purpose of ventilating the Hoosac tunnel. The fan is to be 16ft. in diameter and 8ft. wide, and will be driven by an electric motor. It will have a capacity of drawing 600,000 cubic feet of air per minute. The *Electrical World*, of New York, states that the clearer atmosphere in the tunnel will enable the trains to attain higher speed.

Proposed New Subway in Boston.—A new subway, beginning approximately at the Boston end of the Harvard Bridge and extending to Scollay-square, has been proposed by the Mayor of Boston. The *Street Railway Journal* states that such a subway would cost $2,500,000, and would do away with the necessity of running certain of the surface electric cars, at the same time entirely relieving the congestion which at present exists in and about the present subway.

Wireless Telegraphy to America.—In reply to an inquiry, the Wireless Telegraph and Signal Co. inform us that it is quite correct that they have had negotiations with a syndicate who desire the exclusive rights of connecting England and America by wireless telegraphy. The company is also in close negotiations with a committee appointed by the French Government to make certain experiments with Mr. Marconi's system of telegraphy.

Personal.—Prof. Andrew Jamieson has decided to retire from the position of Professor of Electrical Engineering at the Glasgow and West of Scotland Technical College. It is stated that, owing to the amount of time which he has to give to telegraphic development, he is compelled to devote himself entirely to private consulting work. Prof. Jamieson has been connected with the college for 18 years, and is the senior member of the staff, with a salary of £750. The resignation, we understand, takes effect on July 1 next.

New Use for the Motor Cab.—A novel use for the electric motor cab, or rather for the battery it contains, originates in New York. A surgeon, who wished to make an X-ray examina-

Digitized by Google

tion on a patient living in a house where there was no electric supply, recently hired a motor cab, with the request that an arrangement should be attached to it by means of which the battery could be used to work his induction coil. This was immediately done, and a wire was run from a second storey window of the house in question to the cab, and the examination was successfully performed.

New Central Stations.—The electricity supply station at Calcutta, built by Messrs. Crompton and Co., has been set in operation. It is, we believe, the first public electricity supply station in India, although one has been for some time in operation in Colombo, Ceylon.

The electricity supply works of the Bootle Corporation were formally opened by the Mayor yesterday. The supply is a three-wire system at 2 × 220 volts pressure, with Lancashire boilers, Bellis-Parker steam dynamos, a balancing transformer, and ejector condensers.

Electric Light and Harbour Defences.—In the House of Commons on Monday night, in reply to a question by Col. Kenyon-Slaney, Mr. Powell-Williams said that the electric light service in each section of a fortress was under the section commander, through the officer in charge of submarine mining defences, who was a Royal Engineer. The fire commander was under a Royal Artillery officer, who was also under the immediate orders of the section commander. The general officers commanding were responsible for the efficiency of their harbour defences; and there was no reason for supposing that they were dissatisfied with the electric light service.

Iron and Steel Institute.—As previously announced, the annual meeting of this Institute will be held at the Institution of Civil Engineers, on Thursday and Friday, May 4 and 5, commencing each day at 10.30 a.m. The new president this year is Sir William Roberts-Austen. Among the papers down for reading are:—"On the Use of Blast Furnace and Coke over Gases," by E. Disdier (Bilbao); "On the Solution Theory of Iron and Steel," by Baron H. Jüptner von Jonstorff (Austria); and "On Exploring for Iron Ore with the Magnetic Needle," by Prof. H. Louis. The Queen has graciously consented to accept the "Bessemer" gold medal of the institute for 1899 in commemoration of the great progress made in the iron and steel industries during Her Majesty's reign.

Wireless Telegraphy.—In the House of Commons on Thursday last week Sir R. Penrose Fitzgerald asked the President of the Board of Trade whether, in view of the fact of breakages of the telephonic cables between lightships and the shore having taken place from time to time, he would consider the desirability of adopting the wireless system for one or more of the light vessels recommended by the Royal Commission on Electrical Communication, and not connected by cable at the present time. Mr. Ritchie, in reply, said that the possibility of adopting the wireless telegraph system between light vessels and the shore was a very important question, and was receiving very careful consideration, but he was not yet in a position to express an opinion with regard to it. On Saturday last Mr. Ritchie went down to the South Foreland to inspect the arrangements there, and to witness Mr. Marconi's experiments.

Board of Education Bill, 1899.—The Council of the Association of Technical Institutions has unanimously adopted the following resolutions:—

1. In reference to Section 2 of Clause 3, "That, inasmuch as in some counties, and in most county boroughs the funds available are already fully appropriated for the purposes of technical education it is not, in the opinion of this Council, desirable that these funds should be applied to the payment of the expenses of inspecting schools under this section."
2. "That, in the opinion of this Council, having regard to the fact that the funds assigned under the provisions of the Technical Instruction Acts are not more than adequate for the maintenance and development of technical education, it is essential that for the further purposes of secondary education additional funds be provided."

It has also decided to take steps to endeavour to secure that the interests of technical education shall be adequately represented on the consultative committee named in Clause 4 of the Bill.

International Telephone Trunk Line.—Telephonic communication has been opened between Berlin and Brussels and Antwerp. The distance between Berlin and Brussels is 560 miles, and the line consists of two bronze wires, each of 4mm. diameter. A charge of 8 marks is made for a three-minute conversation.

The long distance telephone line from Sydney to Newcastle, New South Wales, a distance of 104 miles, was opened on January 1, 1898. During its first twelve months' existence, the *Australian Mining Standard* states, the receipts have increased every month, the year's working amounting to £774. This, our contemporary says, gives good interest for the cost of construction, and after paying maintenance and all expenses, will leave a small margin. The line is mostly used by the mercantile, shipping and insurance companies for inquiries regarding shipping.

Patents in Germany.—An interesting return has just been issued by the German Patent Office. The number of patents applied for during the year 1898 was 20,321, showing an increase of 11 per cent. over the previous year. Of these applications only 5,570 were successful, an increase of 130 over last year, but less than the numbers granted in 1895 or 1893, which were 5,720 and 6,480 respectively; 4,950 have expired or become void, compared with 4,573 last year, while at the end of the year the total number of patents in force was 19,991 compared with 19,384 at the end of 1897. Of the patents granted since July 1, 1877, 19·5 per cent. only are still in force. The largest increase in applications during the year is in Class 26, which applies to the production of gas and illumination, a large number of applications in this class referring to the employment of acetylene. In Class 21, for electrical apparatus and machinery, the applications had increased from 931 to 1,199.

The Manufacture of Copper Wire in Japan.—Of the large amount of copper produced in the Japanese mines the greater part has heretofore been exported to and worked up in other lands, some of it being returned to Japan as finished articles. The Japanese naturally have endeavoured to establish the complete industry at home, and, according to the *Electrical World* of New York, one large plant, the Furukawa Smelting Works, has adopted electrolytic refining. Its output for one year since has been about 860 tons, and the works are now to be enlarged to four times the size of the old. It is stated that on the completion of these new works the output will not only satisfy all the domestic demand, but will allow of the exportation of the finished product. This means a large production, as the governmental department of communication alone has used in one year about 660 tons for its wires. The energetic Japanese are now investigating the problems involved in the insulation of wire and the lead sheathing of underground cables, as well as the production of silicon bronze, which has already been attempted.

Automobile Club Exhibition and Trials.—The Automobile Club will hold a show from Saturday, June 17th, to Saturday, June 24th, in the Old Deer Park, Richmond, Surrey. Besides an exhibition of motor vehicles and accessories, the programme will include time tests of vehicles on the track, motor cycle races, hill climbing tests, and competitions for motor vans and omnibuses. The following gentlemen have consented to serve as judges in connection with the show:—Prof. C. Vernon-Boys, Mr. W. Worby Beaumont, Mr. Dugald Clerk, Mr. Bryan Donkin, Prof. Hele-Shaw, Major Holden, Mr. W. H. Preece, Sir David Salomons, Mr. James Swinburne, Mr. Boverton Redwood. Already 56 English, one American, and one Belgian firm have notified their intention to exhibit, subject to satisfactory arrangements being made, and a list of 26 French firms is also given as probable exhibitors. Applications for exhibit space should be made before Saturday next, and entries of vehicles intended to run on the track, before May 18. Copies of regulations, forms, and applications for space, particulars of trials, and certificates, &c., may be obtained on application to the secretary, at 4, Whitehall-court, S.W.

Obituary.—We regret to announce the death, on Tuesday last, of Mr. John Frederick Mills, senior superintendent of the Direct Spanish Telegraph Co. Mr. Mills was born on April 7, 1849, and had, therefore, just completed his 50th year. His introduction to telegraphy was in the old Electric and

Digitized by Google

International Company's service in 1868. He afterwards passed into the Indo-European Co.'s employ, and served at Teheran, Persia. He joined the Direct Spanish Co. in February, 1874, serving first at the Lizard, then at Falmouth, and ultimately took charge of the London station in Gracechurch-street, on the occasion of its opening on Jan. 1, 1868. Mr. Mills had been slightly ailing for some time, but for the past few days his death had been expected, as he was found to be suffering from a serious internal malady. Mr. Mills was much respected by all who knew him, and the Direct Spanish Telegraph Co. has lost an able and devoted servant.

We regret to announce also the death of Prof. O. C. Marsh, who was for many years an associate editor of the *American Journal of Science*. Prof. Marsh, who was in his 68th year, occupied the Chair of Paleontology at the Yale University, and was Vertebrate Paleontologist to the United States Geological Survey. He died at his home in New Haven after a brief illness.

Alloys of Nickel and Iron.—A paper, giving the results of an investigation into the mechanical and physical properties of alloys of nickel and iron, was read by Mr. R. A. Hadfield, before the Institution of Civil Engineers on 28th March. The addition of nickel, either by conferring greater homogeneity or by some particular combination with the iron or carbon present, or both, appears to confer properties upon the alloy equivalent to an annealing, or, if annealing were employed, to reduce the stress produced by forging; it did this even in the annealed material without injuring or seriously lowering the elastic limit. In this respect, therefore, its presence was of considerable practical utility. The well-known Russian metallurgist, Chernoff, had stated that steel was composed of crystals of metallic iron cemented by carbide of iron, the result being that in the case of nickel-iron alloys the inter-crystalline spaces (a subject which had been fully and carefully investigated by Mr. T. Andrews, F.R.S., as regards ordinary steel) were much more completely filled, and the cohesion consequently rendered more powerful. The points of solidification of the cement and crystals were nearer, thus producing or maintaining a more intimate interweaving of the elements. In support of this theory Mr. Hadfield cited the fact that without doubt nickel-iron alloys showed less tendency to segregation than ordinary steel.

The Nernst Lamp.—Our German contemporaries contain the following communication from the Allgemeine Elektricitäts Gesellschaft, of Berlin, who own the patent rights of the Nernst lamp for all European countries (including England) with the exception of Austria-Hungary, Italy and the Balkan States:—"The tests in the laboratory have led to a provisional result, and the important question of initial heating has, we believe, found a satisfactory solution. In consequence, we have commenced the erection and equipment of a new factory for the production of the raw material in uniform quality, which has hitherto been the difficulty, and to manufacture a lamp to meet the requirements of the public. In reply to numerous inquiries from all sides, we can only put the lamp on the market when the efficiency of the new undertaking can assure the prompt execution of orders. Until then we will test the new lamp practically in the installations at our disposal. Prof. Nernst will probably deliver a lecture on his invention in this month."——It has been pointed out to us that the principle of employing refractory oxides in connection with arc lamps, on which the modifications of the Nernst lamp mentioned in our issue of April 7th depend, was alluded to by Herr F. Grünwald in the *Elektrotechnischer Anzeiger*, of December 16, 1897, and February 27, 1898. The principle is, however, older than this, as it dates back, at least, to the "Lampe Soleil," which was exhibited about 10 years ago.

Social Influence of Electric Power Distribution.—The effect of the introduction of steam-driven machinery was to centralise into factories industries which had hitherto been carried on in the artisans' own houses, and it has often been said that as power could be now economically distributed in smaller units by means of electricity, a reverse decentralising movement might well set in in certain trades. At Saint-Etienne there are about 80,000 looms for weaving ribbon, 15,000 of which are in Saint-Etienne itself, and a like number within a radius of 25 miles. These are for the most part owned by small master weavers, each of whom possess only two or three looms, usually worked by himself and members of his family, and it is only in exceptional cases that the machinery is grouped in large factories. The effect of electrical power distribution there has been, not to decentralise, but to prevent the centralisation which must otherwise inevitably have taken place by the building of steam-driven factories. Since the year 1891 the Electrical Company of the Loire has been developed, and its chief business is to supply power for the looms hitherto worked by hand. The extra-mural system of mains now extends over 24 parishes and has a length of 70 miles, over which three-phase current at 5,200 volts is distributed. Thirty transformer stations reduce the pressure to 190 volts for motive power, and 110 volts for lighting. The current for this network is generated at two water-power stations, having a capacity of 900 and 400 H.P., the former with a steam reserve of 600 H.P. In the town of Saint-Etienne there are three steam-driven stations of 600 H.P., 200 H.P. and 100 H.P., generating current directly at low pressure. The total number of looms worked electrically is 2,500 and the average power each require is ¼ H.P. In addition there is a lamp connection of about 8,000 incandescent lamps and about 100 H.P. which is utilised in small workshops.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, April 21st.

INSTITUTION OF CIVIL ENGINEERS.

4 p.m. Repetition of "James Forrest" Lecture, by Prof. J. A. Ewing, F.R.S.

PHYSICAL SOCIETY.

5 p.m. Meeting in the Rooms of the Chemical Society, Burlington House. Agenda: (1) "On the Effect of a Solid Conducting Sphere in a Variable Magnetic Field on the Magnetic Induction at a Point Outside," by C. S. Whitehead; (2) "Demonstration of Richards' Method of Standardising Thermometers," by R. A. Lehfeldt.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.

7:40 p.m. Meeting in the Lecture Hall of the Sunderland Literary Society, Fawcett-street, Sunderland.

MONDAY, April 24th.

SOCIETY OF CHEMICAL INDUSTRY.

8:30 p.m. Extra Meeting of the London Section at the Chemical Society's Rooms, Burlington House, when the President (Mr. G. Beilby) will deliver an Address on "The Relations of the Society to Chemical Engineering and to Industrial Research."

TUESDAY, April 25th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Annual General Meeting of Corporate Members only.

WEDNESDAY, April 26th.

INSTITUTION OF ELECTRICAL ENGINEERS.

9:30 p.m. Students' Meeting in the Library.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "Coal Supplies," by T. Foster Brown.

THURSDAY, April 27th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting, when the President will deliver his Address.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting, when the conclusion of the discussion on Messrs. Duddell and Marchant's Paper on "Experiments on Alternating Current Arcs by Aid of Oscillographs" will be taken. Paper to be read: "Capacity Measurements of Long Submarine Cables," by J. Elton Young.

FRIDAY, April 28th.

INSTITUTION OF MECHANICAL ENGINEERS.

7:30 p.m. Ordinary General Meeting. Paper to be read: "Evaporative Condensers," by H. G. V. Oldham.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Some Features of the Electric Induction Motor," by Prof. C. A. Carus-Wilson.

SATURDAY, April 29th.

INSTITUTION OF ELECTRICAL ENGINEERS.

Students' visit to Central London Railway. Particulars will be given on post-cards.

CONTEMPORARY ELECTRICAL SCIENCE.

[Compiled by E. E. Fournier d'Albe.]

Absorption of Electric Waves.—E. Branly and G. Le Bon recently proved that a metallic enclosure, hermetically sealed, is an absolute protection against the influence of electromagnetic waves. They have since investigated the screening action of certain insulators or feeble conductors such as are met with in the practical work of wireless telegraphy. They operated with hollow blocks of cement, building stone, and sand. In each of the blocks a small cubical chamber was left free, to contain the coherer. It was closed by a thick iron door, through which the wires were conducted. The ringing of a bell indicated the impact of waves upon the coherer. Without a screen, the coherer responded to the exciter at a distance of 40m. and more. It was found that the opacity of the substances tested depended much upon their nature, condition, and thickness. Sand and stone are very transparent, especially in the dry state. Portland cement is very opaque, wet sand almost equally so. To quote a few figures:—Block of cement, with walls 10cm. thick: the bell ceases to sound at a distance of 7m. After drying the distance becomes 12m. The same, 30cm. thick, absolutely opaque while wet. Block of stone, transparent. When wetted for several days the reaction ceases at 25m.

[Branly and Le Bon, *Comptes Rendus*, April 4, 1899.]

Reduction of Phosphate by the Arc.—H. Moissan recently described the preparation, in his electric furnace, of a crystallised calcium phosphide, corresponding to the formula P_2Ca_3. A. Renault publishes his own results, obtained along independent lines. Into an iron or carbon crucible, which serves as a cathode, he introduces a mixture made up of 24 parts carbon and 76 of tricalcic phosphate. The current is introduced by a vertical anode, which is lowered down into the mixture until the arc appears. That requires some 80 or 85 amperes, and as many volts. Vapours containing phosphorus are given off, but these must be absolutely stopped by introducing resistances until the current descends to about 20 amperes. The product obtained is a grey metallic-looking substance, with a reddish crystalline fracture; it consists of calcium phosphide, P_2Ca_3, enveloped in a grey covering of a mixture of carbon and phosphate. The carbon best suited for the purpose is petroleum coke, which contains traces of the heavy hydrocarbons, but does not leave more than about 0·28 per cent. of incombustible residue. The most important property of the phosphide is that it decomposes water, giving non-inflammable phosphuretted hydrogen.

[Renault, *Comptes Rendus*, April 4, 1899.]

Distribution of Terrestrial Magnetisation.—To arrive at a clearer conception of the causes of the unsymmetrical distribution of the earth's magnetism, L. A. Bauer has hit upon the happy expedient of supposing the earth to be, in the first instance, a uniformly magnetised sphere, and then deducting this theoretical magnetisation from the actual magnetisation at corresponding points on the earth's surface. The chart so obtained reveals the existence of three residual magnetic north poles, and three south poles. The strongest of the north poles is situated to the east of Patagonia, the others being in China and the United States. The strongest residual south pole is in the French Congo, and the others are in the Behring Sea and near Tasmania. The most important result obtained is that this distribution of the magnetic irregularities has some connection with the abnormal distribution of temperatures. Roughly speaking, there are secondary north poles in regions which are colder than might be expected from their latitude, while there are secondary south poles in the abnormally warm regions. This would imply that the seat of the abnormal magnetisation is within that layer of the earth's crust which is subject to temperature variations, and that layer is, of course, very thin indeed.

[Bauer, *Terr. Mag.*, April, 1899.]

Diffraction Galvanometers.—The sensitiveness of a galvanometer can, according to P. Weiss, be almost indefinitely increased by constructing it on a smaller and smaller scale, or by employing a greater and greater optical enlargement for reading the angles. But a limit is set by the resolving power of the mirror. A mirror of 1cm. diameter should, according to Foucault's rule, separate two readings 12sec. apart. Practically about 5sec. can be observed, and this, on account of the doubling, means an actual deviation of 2·5sec. But the same author has devised a means of considerably increasing the sensitiveness by diffraction. He uses a mirror 1 by 0·4cm. in area, suspended with its greater length in a horizontal position. The centre of the mirror is blackened, while the ends, 4mm. by 3mm. are left bare. The radius of curvature of the mirror is 4m. It is illuminated by an incandescent filament placed at the centre of curvature. The rays reflected by the mirror produce, at the same distance, the usual phenomenon of diffraction at infinity for the case of two openings. The enlarged image of the filament is seen in the focal plane, traversed by two black fringes, which are sharply defined. On taking the position of one of them as a datum, a micrometric eye-piece will easily discover a displacement of 0·025mm. This is less than a second of arc, and at least four times as sensitive as the usual method.

[Weiss, *Comptes Rendus*, April 4, 1899.]

Electric Lines of Force.—Attempts to illustrate graphically the course of the lines of electric force, after the fashion of Faraday's magnetic lines, usually fail on account of the attraction, charge, and subsequent repulsion of the metallic electrified powder. E. Boudrèaux has, however, succeeded by employing a powdered inferior conductor, sprinkled over a homogeneous and well-insulated non-conducting glass plate. Diamidophenol, crystallised in small needles, answers very well. Cork, elder pith, powdered sugar, and a great variety of other substances may also be employed. The curves are fixed with varnish in the usual way. Three-dimensional curves may be produced in petroleum by means of powdered carbon, but nobody seems yet to have obtained them in air by smoke or dust particles.

[Boudrèaux, *Comptes Rendus*, April 4, 1899.]

New Process of Colour Photography.—Though not marking an advance in electrical science, the grating process of colour photography invented by R. W. Wood is of great general interest. The principle is the following: If the eye is placed in a grating spectrum, the whole grating appears of that colour which impinges upon the eye. If any portion of it has a different interval from the rest, that portion appears of a different colour. If two sets of rulings are superimposed, a mixed colour is seen. The author takes red, green and violet negatives through screens in the usual way, and transfers them to the same position through three gratings which, when superimposed and seen at a certain angle, would give white light. The positive, seen at the same angle, has colours of the original. It can be easily copied.

[Wood, *Phil. Mag.*, April, 1899.]

Electric Charges of Rain and Snow.—J. Elster and H. Geitel have made a series of interesting observations of the electric charges conveyed by rain drops and snowflakes. These observations are not at all easy, being attended by a variety of sources of error. It is not sufficient to catch the drops on a plate or in a vessel connected with an electrometer, since such a plate would be exposed to all the vicissitudes of induction from the earth and the clouds. The authors enclose the plate in a metallic box open at the top. They mount a special conical protector over the plate, to prevent drops reaching it which are spurted from the rim of the box, and may thus have acquired a considerable charge. They also employ a variety of other protective contrivances. Even so, the results obtained are evidently not strictly trustworthy. But one result is very strikingly brought out by simultaneous observations of the aërial potential and the charges of the precipitations. A negative potential of the air is accompanied by a positive potential of the rain drops, and *vice versa*. As the rain goes on the difference increases. For as charges of one sign are withdrawn from the atmosphere, charges of the other sign accumulate in it. The one set of curves is, so to speak, the image of the other.

[Elster and Geitel, *Terr. Mag.*, March, 1899.]

An Exploring Radioscope.—In surgical radiography the orientation of a foreign body is not definite unless it happens to be situated in the perpendicular from the radiant point on to the sensitive plate. It thus may happen that an operation is made in the wrong place. To avoid this danger, A. Londe has designed what he calls an exploring radioscope. It consists of two rings, one of which is placed above and the other below the body to be examined. The axes of the two rings are made to coincide. An X-ray tube will give shadows of both rings, but these shadows will not be concentric unless the radiant point also lies in the common axis. When this is secured the whole apparatus is shifted until the foreign body appears in the centre of the rings on the screen. Points are then marked on the skin at the centre of each ring, and the operator is then sure that the foreign body must be situated somewhere on the line joining the two points. It remains to find whereabouts on that line it is. To do this the X-ray tube is shifted aside a little, thus throwing the foreign body out of the centre. The subject is then removed and a transparent scale inserted in the axis of the rings. That scale will cast a shadow, somewhere on which the foreign body appears. The scale reading against it marks the depth below the skin.

[LONDE, *Comptes Rendus*, March 27, 1899.]

CARBONS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.*

BY FRANCIS JEHL.

(*Concluded from page 857.*)

X.—SOOT OR LAMPBLACK.

The rational working of a carbon factory demands, also, the establishment of works where the soot or lampblack that is used for high-grade carbons is manufactured. Lampblack, soot or amorphous carbon is largely manufactured by heating on a hearth vegetable or mineral matters composed of hydrocarbons. When the vapours are disengaged they are ignited and allowed to burn by supplying just air enough to keep up the combustion—that is, air enough to keep the flames alive, but insufficient to produce complete combustion of the carbon contained or liberated by the gases. The hydrogen, which these substances contain, being its most inflammable part, burns off, leaving the carbon in a powdered or soot-like form. The smoke resulting from this incomplete combustion is allowed to pass through large chambers, where it settles down or condenses. The above are the principles on which large quantities of soot are manufactured, but when a very fine quality of lampblack is desired, oils are generally burned in special lamps, so that they smoke, and the smoke is allowed to condense in a similar manner to that explained above.

Many varieties of apparatus have been designed for producing soot or lampblack by allowing smoky flames to strike some cold surface, on which condensation is effected immediately; this is, however, not necessary, as the quality and efficiency of production can be effected better by allowing the smoke to condense in chambers. On the whole, however, the writer thinks there is plenty of room for further improvement in soot manufacture, and that the long path taken by the sooty smoke in passing from chamber to chamber may yet be avoided. Perhaps favourable results could be obtained by forcing the smoke through water by means of an exhauster, in which water the soot would settle or float on the surface. It would then, of course, have to be dried or calcinated. Another way would be to let the smoke pass through a small chamber in which water was discharged in a spray. The lampblack slush could be collected from time to time, dried and calcinated. Such methods have the advantage of using a small building instead of the long ones now in use, while at the same time there would be a certainty of collecting all the lampblack produced. However, using water in order to catch lampblack has the disadvantage that it is necessary to calcinate the soot afterwards, or at least thoroughly dry it, which means extra labour. As a general thing, lampblack manufacturers in Germany are constrained to locate themselves in the country or woods, because there is such an escape of soot which settles on everything in the vicinity and blackens or soils the neighbourhood. The woods are, therefore, proper places for such a factory, as even in the country where there are crops growing it does damage, as the soot falls or settles on growing fruit in which it gets embedded, thus spoiling it. No doubt many have already seen ears of corn that were spoilt by soot which fell upon it during growth from some neighbouring factory.

The whole theory concerning the formation of lampblack or soot demands simply two conditions:—

1st. That the substance or material employed should be rich in hydrocarbons, which can be rendered into a gaseous form by means of heat.

2nd. That when such hydrocarbons are burnt, the amount of air supplied should be just sufficient to keep up a dull cold flame, whereby an incomplete combustion is produced by the oxidation of the hydrogen only, thus allowing the particles of carbon that are liberated to pass out of the sphere of the flame and settle elsewhere.

It is one of the characteristic properties of carbon that it unites with hydrogen in various definite proportions, thereby forming a large variety of compounds known as hydrocarbons. Many of these compounds, such as lignite, fats, brown fatty coal, tars, pitches, resins, oils, &c., concern us, as they are used in the production of soot or lampblack.

The combustion, when generating soot, must not be so low that these hydrocarbons cannot get decomposed, nor must the combustion be so high that the carbon particles get oxidised and converted into gas. In fact, the quantity of soot produced depends simply upon the regulation of the air that is supplied to the burning matter. We have also seen that we have two ways of collecting the soot; one way by allowing it to condense in chambers, and the other by bringing the flame in contact with some surface—generally a cool one.

No doubt, if condensing chambers were placed in the path of the flue in all our industrial establishments, a large quantity of soot could be caught, and thus a public nuisance abated. Should the draught be hindered by such chambers an exhauster or blower could be used. For carbon purposes, however, such a material would not amount to much, as it contains too many impurities, unless some cheap process could be devised by which it could be cleaned.

Dr. Köhler mentions that Roberts has calculated the amount of soot that overclouds London on a winter's day to be about 50 tons, and that this figure was confirmed by Sir W. Siemens. He also states that in our ordinary stoves at home 100 kilos. (220lb.) of coal produce about 120 grammes of soot, which seems, on the whole, a very small amount. From these figures, however, we will find that the soot escaping in London alone amounts to about 15,000 to 20,000 tons per year.

The writer has already stated that the soot manufactured for electric light carbons, &c., is generally made from such raw materials as fats, brown coals, tars, pitch, resins, &c. One of the principal materials used, however, is tar, which is obtained in large quantities either from gas works or petroleum distillers; in fact, petroleum distilleries have an abundance of this residual matter rich in carbon, which can be utilised in the production of good soot for carbons. A table giving the composition of petroleum (Russian), and based upon commercial outputs is given in Mr. E. T. Carter's "Motive Power and Gearing."*

Now this liquid fuel is a good material from which to make the lampblack or soot used for high-grade carbons, while the petroleum cokes, of which there are plenty in such distilleries, will serve for second grade goods, electrodes, &c.; in fact, petroleum works could turn their by-products to very good account by establishing a carbon factory. The Budapest petroleum works were considering the subject some time ago, and it may yet be realised. The writer knows that at present benzine, as obtained by the petroleum distillers in Hungary, has hardly any value, and that they do not know what to do with it, although some of it is bought for manufacturing the finer qualities of soot from which lithographic and printers'

* From a forthcoming book to be published by *The Electrician* Printing and Publishing Company (Limited). All rights reserved.

* *The Electrician* Series.

Digitized by Google

ink is made. Of course, benzine can only be used in water cooled lamps for making lampblack. If such distilleries are not disposed to manufacture carbons, it would still be to their advantage to produce soot, as they could manufacture that article cheaper than anyone else, with the exception of gas works, where large quantities of tar are also obtained.

The writer wishes to point out the fact that in burning any material, it is of advantage to use only such substances whose flash points are about the same. If a material is used that consists of a mixture of several substances having various flash points, it will be found that, when such a mixture is burned on a hearth, the lighter oils will volatilise and condense in the chambers where the soot also deposits, and the result is that we obtain what is known as "wet soot," which it is necessary to calcinate before using in a carbon factory. If we use such a mixture of oils in a lamp, we shall find that the lighter oils will burn away, while the heavy ones will begin to settle around the wick, which gets partly carbonised and clogs. The writer made some experiments with Russian raw petroleum some time ago, and constructed a special lamp for the purpose of keeping it cool. He found that at first a good soot flame was obtained with regulation, and that only the lighter oils burned away while the heavy ones, whose flashing points are high, remained behind and clogged up the wick, preventing, after a while, the lighter oils from ascending. At the same time the heavy oils began to char, so that the flame was soon extinguished. We see, therefore, it is a matter of some importance to a soot factory to use only such substances that have about the same flash points. Lighter oils should be burned in lamps and heavy ones on hearths. No doubt a process could be devised by which a mixture of hydrocarbons of different flash points could be utilised, and that would be by gradually distilling them in some closed receptacle or retort, converting them into gas, and then burning them with suitable burners.

When employing tar as the raw material, it is necessary that it should be free from water, which would otherwise go over and condense in the soot chambers, while at the same time it interferes with the fire. The tar is in practice warmed up in tanks, and the water settles at the bottom, and by suitable stop-cocks is let off from time to time. The heating of the tar has also another advantage, and that is it makes it more liquid, depriving it of its viscosity. By these means it is easily led through pipes to the hearth where it is burned. It may be mentioned that any old boiler will serve for such purposes. When using oils it is generally unnecessary to heat them, unless they contain matter that may need such heating up. Oils of a low flash point, as has already been mentioned, are generally burnt in lamps, for if burnt on a hearth too much volatilisation matter goes over. Of course, such oils produce a finer quality of lampblack than tar, and are suitable for the best printing inks.

Tar, however, furnishes as good a soot as can be desired for carbons, and as it is cheap, it is largely used. Brown coal also gives a good soot, and is used in many soot factories. As has already been stated, it is very important to produce good regulation of air in a soot works. When too much air is allowed to enter the hearth we obtain good combustion, producing relatively little soot, but one of a fine quality, whereas if too little air is supplied, we obtain more soot, but of a coarser quality. Practice will soon show the amount of regulation that is necessary, and it may be observed that this regulation depends upon the season of the year and state of the weather.

Dr. Köhler gives the following figures relating to the quantity of soot obtained with a given amount of raw material:

100	parts of pitch	gives from	12	to	15	parts of soot.
100	„ tar	„	15	„	18	„
100	„ oil	„	18	„	20	„

The soot is of various qualities, and there remains about 50-60 parts of coke, which is simply used for furnace purposes. Duhamel states that 1,000 kilos. of mineral coal produces about 3·3 kilos. of soot and 400-500 kilos. of coke; Thenius says he received from 400 kilos. of heavy tar oil, 20 kilos. of soot of the first quality, 30 kilos. of soot of the second quality and 20 kilos. of the third and fourth quality. Engler states that in the Black Forest in Germany, where soot is extensively manufactured, they obtain from 100 parts of tar about 25 parts of soot, and from 100 parts of resinous substances 20 parts of soot. Heavy tar oils produce about 25 to 30 per cent. of soot, and petroleum about 20 to 25 per cent. and gas from 4 to 7 per cent. The differences given in the above figures are no doubt due to different modes of operations, that is, the different rates at which combustion is forced in different factories. If we take 20 to 25 per cent. as the efficiency of production we shall be on the safe side. In fact, as soot is used in such large quantities in the manufacture of carbons it cannot be expected that its quality should be similar to that used for fine inks, as no doubt such a difference in quality would show very little in a carbon when burning. The main thing is to obtain pure carbon, and that the cost of producing it will enable the carbon manufacturer to compete with others.

Such hydrocarbons as fat brown coal, tars, pitches, resinous matter and the residuum of oil stills, give us a list of materials that are not expensive and at the same time rich in carbon.

Lampblack, when bought from soot manufacturers, costs about £1. 6s. 7d. or $6.40 per 100 kilos. (220lb.). We can reckon the price of the raw material from which it is produced at—tar at 8s. 4d. or about $0.80 (which is very liberal) per 100 kilos. Taking the efficiency of production at 20 per cent. we would require 500 kilos. (1,100lb.) of the raw material to produce 100 kilos. of soot. This gives us the price the raw material as 16s. 8d. or $4. The writer has calculated that if we add 3s. 4d., or $0.80 per 100 kilos. of soot manufactured, as the costs of labour, interest and redemption it is more than necessary. This gives us the price of soot at about £1 or $4·80 per 100 kilos. We see there is thus a saving of at least about 6s. 7d. or $1.60 per 100 kilos. when a carbon factory manufactures its own soot. This is an important item for a carbon factory, and it is hard for those to compete that have not their own works, as the writer knows from experience. We see also from the above figures that petroleum distillers and gasworks have an especial advantage if they would manufacture soot, as they produce plenty of tar as a by-product. Not alone is there a saving in producing one's own soot, but there is also a considerable saving in freight, as soot factories are at great distance from some carbon works. The writer knows of a carbon manufacturer who pays as much as £30 or $144 for a car load (about 10 tons) of soot. The raw material, however, can be procured generally from a neighbouring town, so that the freight will not amount to much.

A few words may be said in regard to the building of a soot factory. It is advisable never to use any wood in any part of the building where the soot condenses, as the hot gases, in passing through the chambers, will so dry the wood that after a time it will become like tinder and fall or crumble to pieces, while at the same time there may be some danger of it igniting. One may think that such condensing chambers could be easily and cheaply constructed from sheet or corrugated iron; there are, however, some facts that have to be taken into consideration, and in the first place it has been found that soot settles best on rough surfaces, the deposit taking place like snow. Small particles of soot settle on a surface, and, after a while, are formed into flakes, the size of which increases so that they get too heavy to sustain their own weight and fall down. Of course, some of the soot adheres to the walls, and these are also scraped from time to time with a sort of wooden hoe.

When the condensing chambers are constructed of iron, the soot cannot settle well on the smooth sides, for it must be remembered that each flake is composed of several very small particles, which, if they do not settle, will be taken by the draught up the chimney and so escape. Then again, iron being such a good conductor of heat, water and other vapour would easily condense within such chambers, whereas the object in soot making is to have chambers that are always so warm that volatile matter will not easily condense, but will escape by the chimney.

The best, the most practical and economical method is to build the chambers simply with common rough bricks, the sides of which offer a favourable depositing place for the soot. The walls of such condensing chambers should in no circum-

Digitized by Google

stances be finished by coating them with plaster. Such a coating would lessen the efficiency of the depositing surface, while at the same time, when the hot gases circulated through, it may crack and fall down and contaminate the soot. A common unfinished chamber of bricks set in good cement is all that is necessary. The best flooring to give such chambers are flagstones solidly and evenly laid, while the interstices should be partly filled with good cement, in such a way that there is no danger of dislodging such cement when the soot is scraped out together; in fact, the scraping of the soot together should only be done with wooden implements somewhat similar to hoes.

It will be noticed that a new factory will generally produce a much better quality of soot after it has been working for some months. This is due to the fact that in the first months of operation plenty of moisture that is in the walls is driven out by the heated gases. This moisture cools the gases, thereby interrupting the draught and lessening their velocity, which causes the material in the hearth to burn without flame, and permits some of the unburnt products to escape and settle in the condensing chambers, where it and the moisture gets absorbed by the soot.

However, after the condensing chambers have been well dried, it will be found that they keep their heat well, and that the quality of soot obtained is much better. In starting the fires at the hearths, they should be permitted to have all the air that is necessary for complete combustion, and at the same time it is advisable not to start too large a fire in the beginning so that a gradual draught is established while the chambers are slowly heated. After a while, when a good circulation is obtained, we can commence by regulating the damper of the chimney so that the flames have a sort of a dark, red, smoky appearance, while the smoke issuing from the chimney should have a light appearance, that is, no dark, black smoke should appear there. Fuel should be supplied to the fire often but little at a time. Care should also be taken that the supply of air be not so decreased that the combustible begins to swell up, as this may allow unburnt matter to escape. It may also be mentioned that these unburnt gases may cause an explosion by mixing with unburnt air and soot. However, under normal conditions no explosion can occur; the fuel must always be supplied gradually, and not too much of it at a time, and care should also be taken when igniting the fire at the commencement. When it is desired to discontinue such fires notice should always be taken before leaving, that no combustible remains on the hearth; in fact, with precaution and a well regulated service everything will work well. Soot factories generally work day and night with the exception of one day or two in the week when the chambers are allowed to cool and the soot is collected and removed.

LARGE WILLANS ENGINES.

Last Friday we had the pleasure of visiting Messrs. Willans and Robinson's works at Rugby, to inspect the first of the 1,000 H.P. engines which has been completed for the Liverpool Corporation tramways. As this engine was described and illustrated by a scale drawing in our issue of April 8, 1898, and again referred to on November 18th last, it will suffice to recall that it is a compound engine of the "8 V" size, indicating 1,000 H.P. as most economical load, 1,200 H.P. as maximum continuous load, and 1,500 H.P. on emergency, when running non-condensing at a speed of 280 revolutions per minute, and with a normal steam pressure of 160lb. per square inch. It will be direct-coupled to a Siemens 10-pole dynamo, which is to have an output of 1,420 amperes at 460 to 550 volts. Fig. 1 is from a photograph of the engine, which is ready to be tested shortly, and was under steam at the time of our visit.

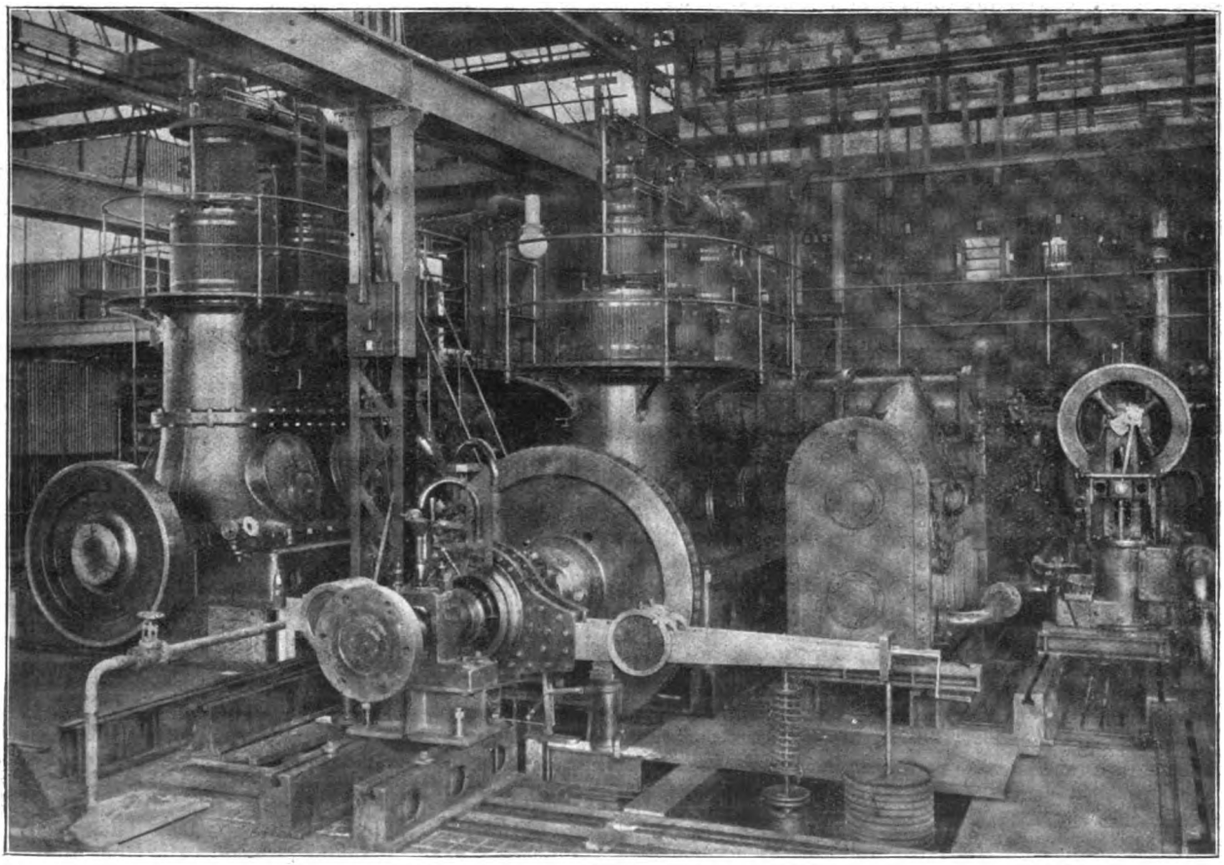

FIG. 2.—470 B.H.P. WILLANS ENGINE FOR CITY AND SOUTH LONDON RAILWAY, COUPLED TO FROUDE WATER BRAKE.

Digitized by Google

Tests were also being carried out on a new 3R engine, one of two ordered for the City and South London Railway. Fig. 2 shows the engine coupled to a Froude water brake. It is designed for an emergency load of 585 B.H.P., its most economical load being 470 B.H.P., at 320 revolutions per minute. According to the guarantee, the governing variation between full load and no load is not to exceed 1½ per cent., and if the whole load is thrown off during a space of 1 second, the momentary variation is not to exceed 5 per cent. Of course, this is largely a question of weight of fly-wheel, and as the engine is at present sans flywheel and sans dynamo the governor trials have not yet been made.

A walk through the works impressed us with the large number of engines of various sizes in process of construction for electricity supply stations, including some large units for St. Pancras. Mr. Robinson informed us that it has been decided to extend the works at Rugby by the addition of a

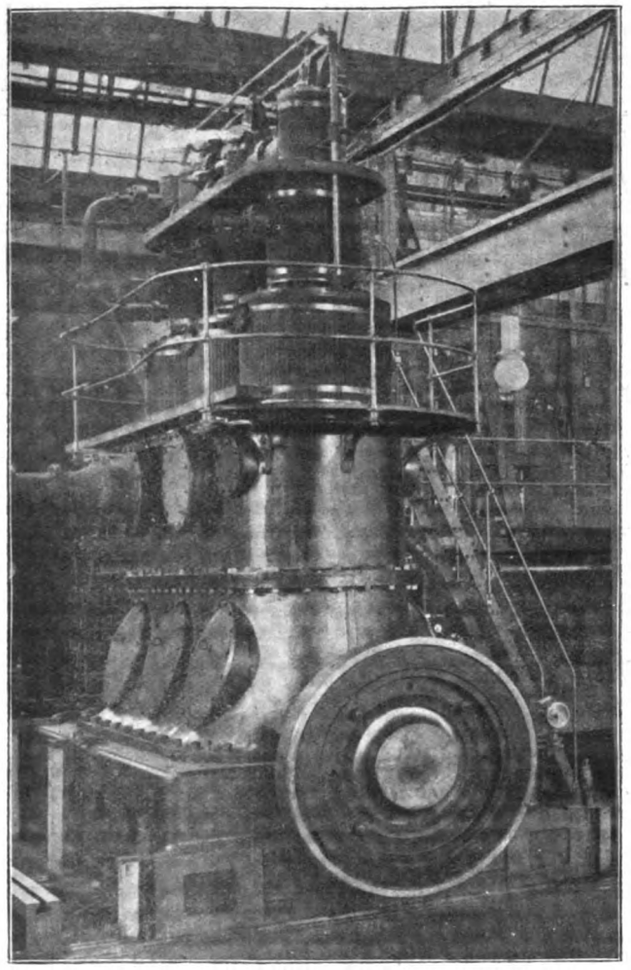

FIG. 1.—1,000 H.P. WILLANS ENGINE FOR THE LIVERPOOL CORPORATION TRAMWAYS.

shop lofty enough to fit engines of 2,500 H.P. and upwards without inconvenience, and that as slow speeds were usually demanded for these large sizes it was probable that double-acting engines would be built. We wish his firm every success in its new venture. Mr. Robinson is also as sanguine as ever with regard to the ultimate success of the double-water tube Niclausse boiler, the manufacture of which is shortly to be moved to new works in Cheshire.

Sand Fire Extinguishers.—It is stated in the *Electrical World*, of New York, that sand will be used to extinguish fire, if there should be one, in the New Telephone Co.'s exchange at Indianapolis. It is to be used because it is less injurious to the electrical apparatus than water or chemicals would be. The sand is stored in a large tank above the exchange room, and is sifted automatically to any or all parts of the building.

EXPERIMENTS ON ALTERNATE-CURRENT ARCS BY AID OF OSCILLOGRAPHS.

(Continued from page 860).

PART II.

SECTION 8.—SEARCH CARBONS IN ARC.

(Fig. 4 and Table IV.)

In the investigation of the distribution of the fall of potential in the arc, two search carbons (2mm. diameter) were inserted into the arc—one search carbon, designated *b*, being 0·5mm. distant from the top carbon, which was designated *a*; the other search carbon, called *c*, was similarly proximate to and distant from the bottom carbon (called *d*) by 0·5mm. Three potential difference wave forms were thus obtained and recorded simultaneously, viz., the waves between *a* and *b*, between *b* and *c* and between *c* and *d*.

Directly after obtaining the above wave forms we, in each experiment, recorded the curves of P.D. between the main carbons and the current through the arc, the search carbons remaining in position in the arc. The experiments were carried out for two different arc lengths, viz., 6mm. and 15mm., and for the same combinations of carbons as in our other experiments. We find in all cases, when we consider the instantaneous values of the distribution of P.D., that they are very similar to those obtained for the direct current arc, and that we may divide the fall of the potential into three parts: a drop at the surface of the + crater, a drop in the arc proper, and a drop at the − crater, the drop at the + crater being always much larger than at the −.

As each crater changes its sign every half period, the difference of potential between it and the search carbon near it is alternately large when the crater is + and small when it is −, which makes the wave forms of this difference of potential very much higher on one side of the zero line than on the other, as is seen in Fig. IV. Thus if a search carbon is connected to the main carbon through an outside circuit, the quantity of electricity which will flow round this circuit will be larger in the direction from the main carbon to the search carbon than in the opposite direction. If a galvanometer be introduced into this circuit its deflection will seem to indicate that the main carbon is always at a higher potential than the search carbon in the arc; and this result is obtained whichever main carbon the search carbon is connected to. Our curves thus explain the above observation of Dr. Sahulka and others, and considerably alter its bearing on the question of the back E.M.F. of the arc.*

The magnitude of the fall of potential in the arc vapour is, we find, nearly independent of the direction of the current, so that the wave forms of potential difference between our two search carbons are almost the same on both sides of the zero line. The instantaneous value of the P.D. between our search carbons is largest at the early part of the period giving a peak on the curve of P.D. between the search carbons, and this peak is very considerable with long arcs (experiments 45, 49, and 53—curve of P.D. between *b*, *c*). *We thus trace the large front peak which we found on the P.D. arc curve for long arcs to the resistance of the gaseous column between the carbons, after cooling during the extinction of the arc. The small back peak obtained with short solid arcs seems to arise at the + crater.*

If we add up the corresponding ordinates of the three curves of fall of P.D. obtained with the search carbons, we ought to obtain the curve of the P.D. between the terminals of the arc, which should be the same as that obtained experimentally; and, as long as the current in the arc is not too small, this agreement is as close as might be expected in view of the fact that some minutes elapsed between recording the search carbons' curves and the corresponding P.D. arc curve. When adding the ordinates of the curves for the cored arc we find that *the chief cause of the characteristic dent in the front side of the P.D. arc curve is the peak in the curve of the drop of the P.D. along the vapour column.* And, since this peak becomes higher with increase of arc length, the dent is moved up the side of the P.D. arc curve, as noticed when considering the effect of length.

All results obtained by means of search carbons in the arc are liable to error, due to the disturbance of the arc by their presence. In our case we noticed that the introduction of the search carbons into the arc caused a sharp ridge to form across the craters, the direction of the ridge being parallel to the nearest search carbon, this latter appearing to protect the crater from wasting away. Another change that the search carbons

Digitized by Google

produced was to increase the P.D. required to maintain an arc of given length and current, this increase being 17 per cent. in the case of a 6mm. solid arc (compare experiments 26 and 42). The power factor was also affected, and, as far as our results go, the power factor is reduced with the solid arc and increased in the other cases by the introduction of the search carbons. One other difficulty which we noticed was that, if by any chance one of the search carbons touched the crater of the main carbon, the arc was extinguished, the crater touched appearing to travel along the search carbon until the arc became of considerable length and then went out. In spite of these difficulties, we think the results show conclusively—

1. *That at any instant the distribution of the difference of P.D. in the alternating arc is similar to that in the direct current arc.*

2. *That the growth of the front peak in the P.D. curve of the long solid arc and the movement of the dent in the P.D. curve of the cored arc are due to the increase of resistance of the gaseous column during such extinction as the arc is lengthened.*

The authors have carried out an immense number of experiments in examining the effect of resistance in series, and in their Paper give no less than 48 sets of curves illustrating this effect. Their interpretation of the more significant changes in the wave form is so clearly set out in the text, that we confine ourselves to reproducing only two of these curves, viz., those corresponding to experiments 54 and 55. These curves are, it will be noticed, for arcs of 1mm. length between solid carbons. In experiment 54 the resistance in series was 0·96 ohms, the potential difference of the alternator 51·5 volts, of the arc 42·1 volts, the power absorbed by the arc 360 watts, and the power factor 0·58, the arc hissing and unstable. In experiment 55 the alternator potential difference

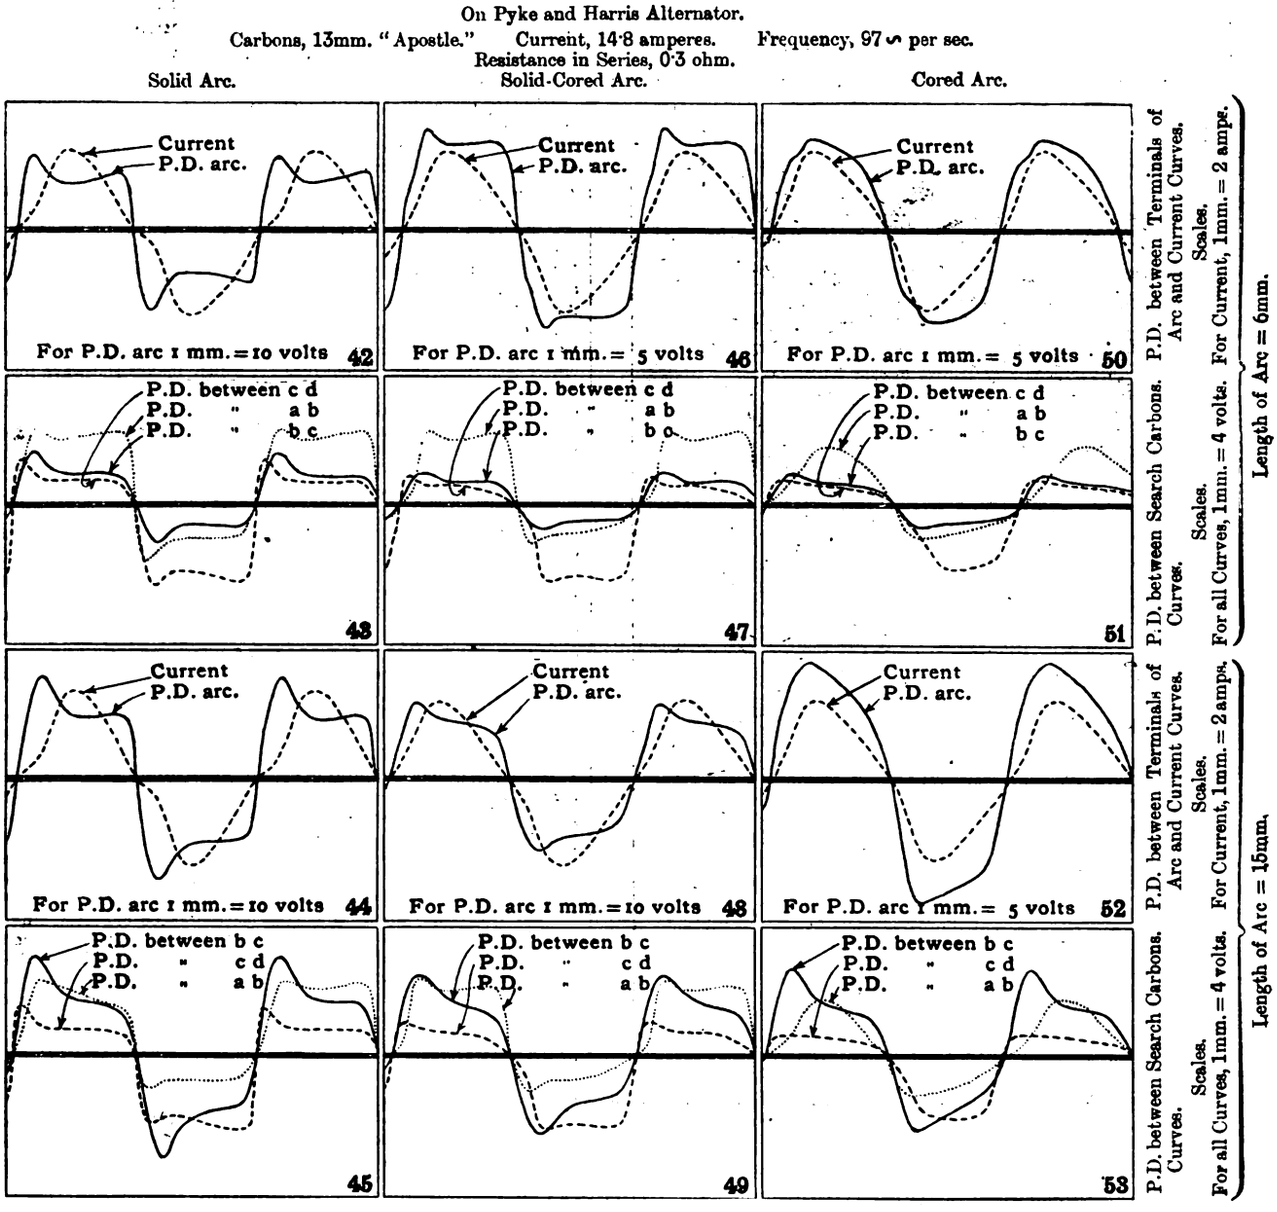

FIG. 4.—Search Carbons in Arc.

SECTION 4.—EFFECT OF RESISTANCE IN SERIES.

Mr. Frith, in his Paper before the Physical Society, said that the effect of the arc on the wave form could be destroyed by placing a large resistance in series with the arc, and he pointed out the great importance of this observation as affecting efficiency tests of alternate current arcs. The curves with resistance in series obtained by Mr. Frith differ, however, very much from any of those given by M. Blondel; and the latter has not published any series of strictly comparable results to show the effect of change of resistance in series. We have therefore carried out a complete investigation of the subject for several different arc-lengths.

In our experiments we kept the size and kind of carbons, the arc-length, the current, and the frequency constant, the resistance in series being varied by small steps. The current in all cases was kept constant by changing the dynamo excitation. The experiments were carried out on both alternators and with the usual combinations of carbons.

was 92 volts, the arc pressure 48·5, power 404 watts, and the power factor 0·63, with hissing going on. Both experiments were with the Ferranti machine.

The range of resistance used with the Ferranti machine was from 0·3 to 3·9 ohms; but it was found impossible to burn the solid and solid-cored arcs with 0·3 ohm. in series; the cored arc, however, could be maintained, though it was not very stable. With about one ohm in series all three arcs could be maintained, the solid arc being none too steady, however.

Increasing the resistance in series has, with the solid arc, increased the peaks on the P.D. arc wave and reduced the time during which the current remained small (experiments 54 and 55); with the solid-cored and cored arcs, however, the effect was not very noticeable.

Experiment 54 is of interest, as it was made with the arc having the lowest power factor for which we have recorded the periodic curves, the

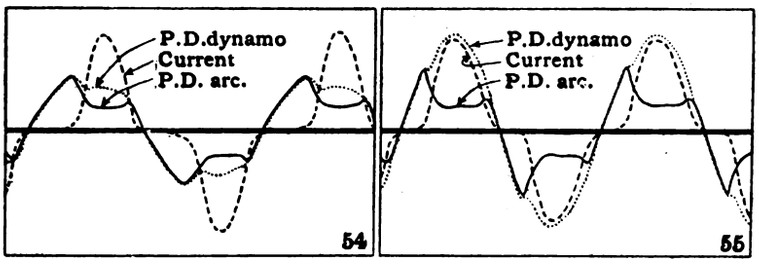
Digitized by Google

power factor being only 0·58; yet it will be noticed in the curves that there is no angle of lag, in the ordinary meaning of the term, as both the P.D. between the arc terminals and the current are zero at the same time. The idea that as the power factor is low there must be a considerable difference of phase between the P.D. and current seems still to exist in spite of all that M. Blondel has written on the subject, and in spite of the periodic curves he has published, none of which show any appreciable phase difference between P.D. and current. It is, perhaps, needless to add that, as yet, in all our results we have not come across a case where the curves are sensibly out of phase: and we believe that in those cases, where previous experimenters thought they obtained a considerable angle of lag between their periodic curves of P.D. arc and current, this erroneous result was introduced by their not recording the two curves simultaneously.

Returning to experiment 54, it is to be noticed that the curve of P.D. between the dynamo terminals is also distorted by the arc to a considerable extent, the distortion being greatly reduced by increasing the resistance in series (experiment 55). On the Pyke and Harris machine the range of resistance was from 0·3 to 10·2 ohms. In this case, owing to the inductive nature of the machine, it was possible to burn all the arcs with 0·3 ohms in series. As before, increase of resistance in series with the solid arc tends slightly to increase the peaks on the P.D. arc wave, the effect being most marked in the 1mm. arc. *The effect on the current wave was in all cases to make it more like the open-circuit wave form of the alternator used*, and this is well illustrated by the similarity of the current waves with 10 ohms in series with the arc to the open-circuit curve of the dynamo.

Turning next to the R.M.S. values of the P.D. between the terminals of the arc, in all cases they are reduced by increasing the resistance in series with the arc, except for the 1mm. solid arc, this reduction in P.D. being as large as 9 per cent. for the 3mm. solid arc.

The power factors with the Ferranti alternator all tend to increase with increase of resistance in series, while those with the Pyke and Harris machine decrease for the solid and solid-cored arcs, and are almost unaffected for the cored arcs. These changes in the power factors are chiefly due to the current waves becoming more like the open-circuit



Scales: For P.D. Dynamo, 1mm. = 10 volts. NOTE.—Scale of Time not the same as usual.

„ Current, 1mm. = 2 amps.

FIG. 5.—Effect of Resistance in Series.

curves of the alternators as the resistance in series is increased, while the P.D. waves for arcs of medium length do not alter very much. Thus, while we have not been able to produce the considerable changes in the shape of the P.D. arc wave observed by Mr. Frith, *our results confirm his conclusion that the efficiency of the alternate current arc is affected by the amount of resistance in series with it.* For change of resistance in series, we find, considerably modifies the current wave, and Messrs. Rössler and Wedding and others showed that the efficiency is dependent on the shape of the current wave form. Mr. Frith's remark, that the arc has the power of automatically converting any wave form into the one best suited to its requirements, is not, however, borne out by our experiments (*see* experiments 54 and 55).

SECTION 5.—EFFECT OF FREQUENCY.

A very large range of frequencies being in use in the alternating supply systems of this and other countries, and there being exceedingly little available data as to the effect of change of frequency alone on the behaviour of the arc, we carried out a series of experiments over a range of frequencies from 29·2 to 200 ∽ per second, and this range embraces most of the frequencies that are in practical use. At the present time, in this country nearly all the public supply stations use frequencies between 50 and 100 ∽ per second; but there is a tendency towards lowering the frequency so as to be better able to operate alternate-current motors.

To make our experiments as far as possible comparable one with the other, we brought the current back to a fixed R.M.S. value by varying the dynamo excitation after each change of frequency, while the arc length and all the other conditions of the circuit remained unchanged. To obtain the range of frequency from 29·2 to 200 ∽ per sec., we were obliged to use both the alternators, the results for the range 29·2 to 127 ∽ per sec. were, however, obtained on one single machine and arc, thus strictly comparable one with the other, while the results for 100 and 200 ∽ per sec., though not obtained on the same alternator, lead us to the same general conclusions.

The chief effect of reducing the frequency is, in all cases, *not only greatly to increase the actual time during which the current remains small in each period, but also to increase the fraction of the period during which it is so.* Accompanying this there is, as we should expect, seeing that we have kept the R.M.S. value of the current constant, a considerable increase in the maximum value of the current with decrease of frequency, and this increase of the maximum value has caused the low frequency *solid* arc to hiss badly and become so unstable that we were unable to obtain results below a frequency of 57 ∽ *per sec.* The *solid-cored* arc was slightly unstable at 46 ∽ *per sec.* The *cored* arc, however, did not become unstable at 29·2 ∽ *per sec.*, the lowest frequency we tried; but the light of the arc was exceedingly unpleasant to the eyes at this low frequency. When the R.M.S. value of the current, the length of the arc, &c., are kept constant, lowering the frequency increases the R.M.S. value of the P.D. for the solid arc, but reduces it for the cored arc, the effect with the solid-cored arc being apparently *nil.*

The power factor in all cases which we have tried was reduced by lowering the frequency.

In one of his first Papers on the alternate current arc, M. Blondel stated that, as the current had a small value for a long time with low frequency arcs, he expected that the efficiency would be smaller with low frequencies than with high ones. Experiments,* however, made subsequently, convinced him that the opposite was the case. This conclusion was also arrived at by Professor Fleming and Mr. Petavel,† and is borne out by some experiments made by Messrs. Cameron and Hecht, at the Central Technical College, who measured the luminous efficiency of some of the arcs. For the latter found that with the solid arc a reduction of frequency from 127 ∽ per sec. to 57 ∽ per sec. increased illumination per watt by 50 per cent., and that for the cored arc a reduction of frequency from 127 ∽ per sec. to 46 ∽ per sec. increased the illumination per watt by 10 per cent. Thus, *as far as efficiency is concerned, a reduction of frequency is very advantageous;* there is, however, a practical limit to this reduction due to the instability of the arc with low frequencies.

SECTION 6.—ARCS ON TRANSFORMERS.

In this section the authors give the result of their investigations to determine whether the reactions on the wave forms still take place when the arc is run off a transformer, and if so, whether these reactions are reflected in the primary circuit of the transformer.

We find that the reaction of the arc on the wave forms of the circuit, when supplied with current by the secondary of a constant P.D. transformer, is similar to what we have found when the circuit is supplied by the alternator direct, and that the characteristic forms of the P.D. arc and current waves *are transmitted through this transformer to its primary circuit*, so that the P.D. and current curves for the two circuits are very similar. One point of difference which we noticed with the solid arc is that while in the secondary circuit the current curve keeps along the zero line for a time as usual, in the primary the curve approaches the zero at a small angle, this being due to self-induction.

As was to be expected, however, the authors find that with a *constant-current* transformer the distortion of the potential difference wave form *is not transmitted* to the primary circuit, in consequence of the much greater magnetic leakage in such a transformer, as compared with one designed for constant pressure on the secondary. With both classes of transformer the arc was found to react on the potential difference wave between its terminals and the current in the ordinary way.

SECTION 7.—ARCS BETWEEN DIFFERENT MAKES OF COMMERCIAL CARBONS.

After experimenting on the same alternator with the same excitation, first with a constant resistance, and afterwards with a constant self-induction in series with the arc, the authors find that—

The characteristic reactions of the arc on the wave forms are seen to occur in all cases, being modified, however, in amount by the nature of the carbon, and by the presence of impurities.

We conclude from these experiments that although the amount of the reaction of the arc on the wave forms varies to a certain extent, from one make of carbons to another, yet the main features are in all cases so similar that we can deduce what will be the effect of the change of any variable on the reaction of one make of carbons from the known effect on the reaction of another make. It is well known that any change in wave form changes the impedance of an inductive coil, and as the shape of the wave depends on the nature of the carbons, we might expect the impedance of an inductive coil in series with an arc to depend on the kind of carbons in the arc; and that this is the case is evident from the observed values of the impedance of the choking coil used in experiments 135 to 141 (*see* also experiments 5 to 8 *ante*). This change of impedance, though small, may affect the the design of the regulating coils for arc lamps.

SECTION 8.—ARCS BETWEEN ONE SOLID CARBON AND ONE CARBON CORED WITH A FOREIGN SUBSTANCE.

This section of the Paper contains many interesting results of experiments prosecuted in the hope of discovering some substance for the core which, while not impairing its luminous efficiency, would reduce its reaction on the wave forms. This primary object was unsuccessful, but, amongst other things, it was found, as may be gathered from the table on the "Effect of Soaking Carbons in Aqueous Solutions," that:—

It is possible considerably to reduce the P.D. necessary to maintain an arc, of given length and current, without affecting the appearance of the arc, by treating the carbons with a potassium salt, and it seems more than probable that the low P.D. and steady burning properties of the cored arc are largely due to the presence of potassium silicate in the core. A remaining trace of this salt probably accounts for the low P.D. required for the arc between a solid and a hollow carbon, which hollow carbon was made by drilling out the core of a cored carbon. When foreign substances, which are not in, or reduced to, the metallic state, are present in the arc, they produce a reduction of the P.D. between the carbons, for a given length and current, and generally reduce the reaction on the wave form and increase the power factor.

ELECTRICITY WORKS ACCOUNTS.

Kingston-upon-Thames Municipal Electric Supply Works.

It is disappointing to find that the accounts for the 1898 working of the Kingston-on-Thames undertaking hardly indicate a fulfilment of the promise contained in the 1897 accounts; at least, as regards accession of business and financial results. A comparison of the 1897 with the 1896 accounts showed a drop in the ultimate deficit of from £1,326 to £792, a 34·8 per cent. increase in the equivalent lamp connection and a rise of nearly 25 per cent. in the output. As may be noticed from our table this week a similar comparison of the last two completed years of working shows an increased deficit, viz., £1,112, an increase in the equivalent lamp connection of barely 29 per cent. and an increased output of only 19·6 per cent.

The management charges for 1898 show a diminution over those of 1897, but the same cannot be said of the generating costs in consequence of increases in the fuel and "repairs and maintenance at the station" items. The result is that the total costs per unit are but slightly lower than those of the previous year, which were higher than the average of stations of equal output. No doubt these high costs are due in great measure to the heavy fuel bill, which constitutes *the* burden of the concern. At 1·8d. per unit, this fuel charge is more than double the average obtained in municipal stations of similar output in 1897.

The working profit for the year was £1,221. After paying £1,231 into the sinking fund and £1,102 as interest the deficit is £1,112.

The following figures show the progress made since supply was commenced in 1898:—

Year.	No. of consumers.	Equiv. 8c.p. lamp connection.	Output units sold Total.	Units sold to consumers.	Max. load K.W.	Rev. Total.	Expenditure. Total.	Working profit.
1893–4	77	4,000	128,267	44,642	130	£1,985	£2,573	– £587
1895	99	4,800	134,084	67,446	136	2,442	2,704	– 262
1896	129	6,825	155,681	88,620	152	3,013	2,712	+ 301
1897	163	9,200	194,268	126,835	203	3,929	3,062	+ 868
1898	211	11,856	232,370	164,413	245	4,701	3,480	+1,221

Burton-upon-Trent Municipal Electric Supply Works.

It is satisfactory to find that the progress, though slow, of the Burton undertaking is being maintained. Since 1897 the expended capital has increased from £30,472 to £31,852, the increased expenditure being chiefly on plant.

Additional consumers to the number of 33 and lamps to the equivalent of 1,800 have been added during the year, while the output has risen from 79,492 units to 108,290, or 36 per cent.

The total revenue, at £2,590, averages 5·74d. per unit, and, like the costs, at 3·7d. per unit, are high, even for the small output. In spite of substantial rises in the management and distribution costs, the total costs have fallen from 4·14d. to 3·7d., generating costs having dropped from 3·55d. to 2·87d. The fuel costs at Burton are very low, due, no doubt, to the advantage (in this respect) of running the electricity and gas works in proximity, and under the same interest and management.

The working profit comes out at £921. As at Kingston, nothing, apparently, has been provided for depreciation. A payment of £992 towards repayment of loans, and £860 as interest, leaves a deficit of £931.

We include a table indicating the history and progress of the electricity supply undertaking at Burton since the commencement of operations:—

Year.	No. of consumers	Equivalent lamp connection.	Number of units sold.	Expenditure. Total.	Revenue. Total.	Working profit.
1894	53	4,130	19,291	£844	£529	– £315 (loss)
1895	68	5,472	40,094	1,343	1,051	– 292 (loss)
1896	80	6,132	58,189	1,232	1,521	+ 289 (gain)
1897	104	7,786	79,492	1,369	2,073	+ 704 (gain)
1898	137	9,586	108,290	1,669	2,590	+ 921 (gain)

The following is a list of electric supply works the accounts of which have been analysed, together with the dates on which statements and analyses of accounts have appeared:—

Aberdeen (Municipal)	1899	Jan. 6	Kensi'gton & Knightsbr' (Co.)	'99	Mar. 3

The Electrician.

The Oldest Electrical Journal (established as a weekly Journal 1861—1878)

Published every Friday, Price Sixpence; Post Free, Sixpence Halfpenny

Editorial Publishing and Printing Offices,

1, 2 & 3, SALISBURY COURT, FLEET ST., LONDON.

Telephone: 949 Holborn. *Telegrams:* "Electrician Newspaper London."

All Letters relating to Subscriptions, Advertisements, and other business matters should be addressed to the Publisher, "The Electrician," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "The Electrician" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co.'

All Editorial letters to be addressed to The Editor.

All letters for insertion in "The Electrician," *or containing questions, must be accompanied by the name and address of the writer as evidence of good faith. No notice whatever is taken of anonymous communications.*

"The Electrician" *is published every Friday morning, in time for the morning mails. It is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices, as above.*

New Volumes of "The Electrician" *commence in April and October.*

Subscription Rates.—The Rates for Subscriptions to "The Electrician" are as under:—

	Year	Half-Year	Quarter	
United Kingdom	26s. 0d.	13s. 6d.	7s. 0d.	Post free, payable in advance.
Postal Union	30s. 6d.	16s. 0d.	8s. 0d.	

"The Electrician" *offers exceptional advantages to Advertisers.* It has by far the largest circulation of any English Electrical paper, and circulates all over the World. *This statement is guaranteed.*

Advertisement Rates, &c., forwarded on application to the Publisher.

Trade Advertisements *intended for the current issue must reach the Office not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday. Wrapper Advertisements by Wednesday morning.*

Official Announcements, Auctions, *and* Small Advertisements *accepted up to 6 p.m. on Thursday.*

ELECTRICAL BOOKS AND PUBLICATIONS.

All Books, Newspapers, and other publications can be ordered direct of "The Electrician" *Printing and Publishing Company, Limited. The well-known* "Electrician" Series *of Standard Electrical Works at present consists of—*

ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS. By J. Elton Young, M.I.E.E. Price 10s. 6d., post free; abroad 11s.

THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING. By Messrs. H. K. C. Fisher and J. C. H. Darby. Price 6s. net; abroad, 6s. 3d.

BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH. Edited by C. E. S. Phillips. With an introduction on the history of Crookes Tube and Röntgen Ray work, and a chapter giving "Practical Hints," on the subject.

THE POTENTIOMETER AND ITS ADJUNCTS. By W. C. Fisher. Price 6s., post free.

LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS. By F. C. Raphael. Price 5s., post free.

MOTIVE POWER AND GEARING. By H. Trueliett Carter. Price 12s. 6d., post free.

SUBMARINE CABLE LAYING AND REPAIRING. By H. D. Wilkinson. Price 12s. 6d., post free.

ELECTRICAL LABORATORY NOTES AND FORMS (Elementary and Advanced). Arranged by Dr. J. A. Fleming, M.A. F.R.S. Printed particular on application.

ELECTROMAGNETIC THEORY. By Oliver Heaviside. **Vol. I.** Price 12s. 6d., post free 12s. *Vol. II. is nearly ready.*

THE ALTERNATE CURRENT TRANSFORMER IN THEORY AND PRACTICE. By Dr. J. A. Fleming. VOL. I.—THE INDUCTION OF ELECTRIC CURRENTS. New Edition. Price 12s. 6d., post free. VOL. II.—THE UTILISATION OF INDUCED CURRENTS. Price 12s. 6d., post free.

ELECTRIC LAMPS AND ELECTRIC LIGHTING. By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. 96 original Illustrations, price 7s. 6d.

MAGNETIC INDUCTION IN IRON AND OTHER METALS. By Prof. J. A. Ewing, M.A. Price 10s. 6d., post free. Also in German, 8s. 6d., post free.

ELECTRIC MOTIVE POWER. By A. T. Snell. 10s. 6d., post free.

THE ART OF ELECTROLYTIC SEPARATION OF METALS (Theoretical and Practical). By Dr. George Gore. Price 10s. 6d., post free.

ELECTRO-CHEMISTRY. By Dr. George Gore. Price 2s., post free.

PRACTICAL NOTES FOR ELECTRICAL STUDENTS. By A. H. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free

DRUM ARMATURES AND COMMUTATORS (Theory and Practice). By F. M. Weymouth. Price 7s. 6d., post free.

THE INCANDESCENT LAMP AND ITS MANUFACTURE. By Gilbert S. Ram. Price 7s. 6d., post free.

A POCKET BOOK OF ELECTRICAL ENGINEERING FORMULÆ. By W. Gruphl and H. M. Kilgour. Price 7s. 6d. net, post free 7s. 9d., abroad, 8s.; large-paper edition, 12s. 6d., post free. New edition in the press.

"THE ELECTRICIAN" PRIMERS. In Two Vols. Paper covers, 2s., post free, 2s. 2d., each; strong cloth, 2s. 6d., post free, 2s. 9d. each. Single Primers, 2d., post free, 2½d.

WIRELESS TELEGRAPHY: Signalling across Space without Wires by Electric Waves. By Dr. O J. Lodge. Enlarged Edition. Price 2s. 6d. net.

A DIGEST OF THE LAW OF ELECTRIC LIGHTING, TRACTION, &c. By A. C. Curtis-Hayward, B.A. Price 3s. 6d., post free.

THE MANUFACTURE OF ELECTRIC LIGHT CARBONS. A Practical Guide to the Establishment of a Carbon Manufactory. Price 1s. 6d. post free.

THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS. Edited by W. W. Beaumont. Price 2s. 6d., post free.

FULL CATALOGUE POST FREE ON APPLICATION.

"ELECTRICIAN" SERIES FORTHCOMING BOOKS.

ELECTROMAGNETIC THEORY, VOL. II.—By Oliver Heaviside. The second volume of this important work is in an advanced stage, and will be ready shortly.

PRACTICAL TELEPHONY.—By Dane Sinclair and F. C. Raphael.

PRIMARY BATTERIES.—A work on this subject will shortly be published bringing the theory and practice of the Primary Battery up to date. The book will be fully illustrated.

SECONDARY BATTERIES.—By E. J. Wade. Fully illustrated. The Author in this work will deal briefly with the theory and fully with the chemistry, design, construction and manufacture of secondary batteries or accumulators.

"THE ELECTRICIAN" WIREMAN'S POCKET-BOOK.—Edited by F. C. Raphael. "The Electrician" Company will shortly publish a valuable pocket-book for the use of those engaged in wiring work, both external and internal.

CARBONS FOR ALL ELECTRICAL PURPOSES.—By Francis Jehl. A work will shortly be published dealing fully with the manufacture of carbons for all electrical purposes. The book will illustrate the machinery and apparatus used in carbon manufacture on the Continent and in America, and will give the latest practice in this important subject.

SPECIAL NOTICE.

The present number of "The Electrician" completes Volume XLII. With next week's number will be issued (Gratis) the Index to the Volume.

EARTH CURRENTS AND ELECTRIC TRACTION.

Even the most uncompromising advocates of electric traction, and the deriders of terrestrial magnetic research, must allow that Prof. Rücker made the most of his case for magnetic observatories in his discourse at the Royal Institution last Friday evening. Some of his audience came, we are sure, prepared to hear a violent diatribe against the use of earthed returns for electric traction currents, illustrated by experiments to show its effect on delicate magnetic instruments, and followed, probably, by a strong advocacy of insulated return conductors, or of polyphase or surface-knob traction systems. But Prof. Rücker followed a wiser course, and one which rendered his exposition much more acceptable than would have been a polemical lecture on the subject so near to his heart. He first endeavoured to arouse in his hearers an interest in the magnetic research that is so frequently scoffed at; and, having thoroughly succeeded in showing that, besides being an engrossing subject, it is also one involving important issues to science, he only then spoke of the disastrous effect stray earth currents had already had on the work of some magnetic observatories, and most of his hearers must have been in sympathy with him when he ultimately expressed the hope that the continuous observations carried on for 40 years at Kew might not be abruptly terminated as those at Washington and Toronto have been.

The first experiment Prof, Rücker performed was to show how magnetic iron ore, as well as the metal itself, lost its magnetic properties when heated. He balanced a piece of glowing basalt in a scale, a magnet being placed below it, and as soon as the basalt had cooled sufficiently the beam of the balance was pulled down. This led to a lucid exposition of Mr. Henry Wilde's hypothesis to account for the earth's magnetism, and a description of the model he had built to illustrate and in great measure to prove it. Those who have followed the work done in terrestrial magnetic research will remember that Wilde had at first endeavoured to imitate the magnetic action of the earth by a globe containing two magnetising coils of wire inclined at an angle, but had failed by this means to make it act properly upon a magnet on the surface until he conceived the idea of covering the seas with sheet iron. Then, however, he reproduced the effect to a remarkable degree of accuracy, for not only was the general polarity reproduced, but also the

Digitized by Google

more important variations of the magnetic declination at different points of the earth's surface. The reason of this result Prof. RÜCKER explained as follows: Assuming that the earth's crust is of magnetic material, it can only be magnetised to a certain depth below the surface; for, as the depth and, therefore, the temperature increase, the iron ore loses its magnetic properties. But it is known that at great depths the temperature of the ocean is exceedingly low, and therefore the shell of the earth, being cooler beneath the seas, would have greater permeability and be permeable to greater distances from the surface. The hypothesis appears as plausible as it is ingenious, and we need hardly point out that, if it be correct, the continuous magnetic observations now being carried out may some day prove of inestimable importance to geologists and astronomers as well as to physicists.

It must be remembered that what Prof. RÜCKER and his supporters ask for is not by any means a suppression of electric traction in the neighbourhood of magnetic observatories, but merely that, where the proximity is unavoidable, precautions should be taken to obviate the leakage of large currents through the earth. It appears that the effect of the motors themselves is not so distressing. Opponents of any such restrictions being placed on electric traction schemes often aver that the case is similar to the historical fight between the traction and the telephone companies, and that it rests with the disturbed party to shield themselves from the disturbances. In the case of the telephone industry we are entirely in accordance with this view, as the shielding can be perfectly carried out, and has, in fact, resulted in telephony being made more efficient than before the invasion of the trolley car. Again, in mere physical laboratories, delicate instruments can certainly be shielded to a considerable extent from artificial magnetic storms without, and galvanometers of the d'Arsonval type, which are practically unaffected by such disturbances, are now constructed of such sensitiveness that they can take the place of suspended magnet galvanometers for nearly all purposes. But magnetic observatories come under an entirely different category, for they are threatened with having the actual quantities they wish to measure changed to abnormal values. The suppression of earth returns, if a continuous-current system is used, as will be done at Kew, or the employment of another system of traction within a certain radius of the observatory, can at most increase the capital expenditure, and perhaps also to some extent the working costs of the line; and if these sacrifices are made, as they often are, in deference to so-called "æsthetic" objections of municipal bodies, surely they can be made where much more important issues are at stake.

THE ZIPERNOWSKI-DÉRI-BLÁTHY TRANSFORMER DISTRIBUTION PATENTS.

An interesting patent will expire on Thursday next, and a still more interesting one completed its fourteen years' life on March 16th last. The pair constitute the famous Zipernowski-Déri-Bláthy transformer distribution patents, which it has been claimed cover the general principles governing practical transformer construction and alternate current distribution. Especially during the last year of its life has the patent No. 5,201 of 1885 become prominent, through the speculation which Mr. Martin Rucker, the some-time bicycle financier, has embarked in. A perusal of this patent (given in its latest amended form below) will show that, if the patent is not invalid owing to "prior common knowledge," it might be deemed to cover the modern method of distributing alternating currents by means of transformers connected in parallel on constant pressure mains. As a legal action is pending, we will offer no opinion on that subject at present.

Mr. Rucker, having acquired the patent, and it having been duly brought into a presentable shape by liberal disclaimers, sought about a year ago to obtain royalties from undertakers of alternating current supply. He commenced, perhaps unwisely for his purpose, with the London Electric Supply Co., whose knowledge of patent law in general, and transformer patents in particular, is particularly complete by its long experience in fighting the old Gaulard and Gibbs patent some years ago. This Company took the wise step of consulting with the other large alternating current companies, who agreed (with one notable exception) to support it in its defence; and subsequently, it being considered that some of the municipal electric lighting concerns in the provinces had also a large stake in the question, the Municipal Electrical Association was approached and agreed to join forces with the companies. A representative committee was formed, with Mr. Stewart Bain as chairman, and the matter was fully gone into. Prominent counsel were consulted (among them Mr. Fletcher Moulton, Q.C.), and a careful defence prepared. There was considerable delay between the serving of the writ and the action being put down for trial, leading some to think that it had been abandoned; but we believe the defendants have done all in their power to press it forward, with the result that a date for the hearing should shortly be fixed.

As has been mentioned, the patent underwent considerable amendation as recently as April, 1897. The provisional specification included five diagrams and was longer and covered much more ground than the complete specification in its present form; the complete specification originally contained four illustrations, but these have now been reduced to one. Originally there were three claims; but the first, relating to the construction of the generator and the regulation of its current, and the third, relating to "the groupment of the coils" on the transformers, were wisely disclaimed, leaving only one claim. It is a matter for surprise that there was not more opposition to the amendment of the patent. One company, we believe, threatened to oppose the amendment, but the opposition was subsequently withdrawn, a free license, we understand, being accepted as compensation. This company is, needless to say, not joining in the present combination. We have been told that one municipality represented on the committee, decided, on the recommendation of their town clerk, to offer Mr. Rucker a sum as composition for his claim upon them, but we can hardly credit the report, as in a case like this so much depends on the presentation of an unbroken front.

Needless to say, for the benefit of the industry, we wish the allied companies and local authorities every success. Perhaps this case may lead to a *rapprochement* over other issues.

The following is the text of the two patents. Of the first, space will only allow us to give the amended complete specification. This patent, it is seen, was granted to Messrs. Zipernowski and Déri. The second patent, granted to Zipernowski, Déri, and Bláthy, we give in full, in its original form. It was filed only as a complete specification, and was subsequently amended by the omission of the first claim, and the alteration of the numbers of the second and third claims to the first and second:—

[No. 3,379*, March 16, A.D. 1885.]

COMPLETE SPECIFICATION AMENDED.

Improvements in Distributing Electricity.

I, William Phillips Thompson, of 6, Lord-street, Liverpool, do hereby declare the nature of this invention (a communication from Carl Zipernowsky and Max Déri, of Budapest, Hungary), and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

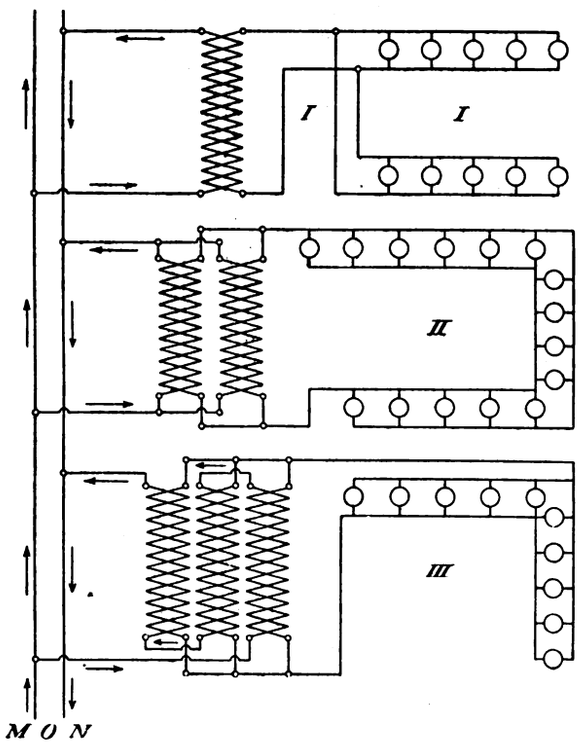
For some time past induction coils, consisting of two coils or layers of insulated copper wires, with a common iron core similar to the Ruhmkorff apparatus, have been used for the transformation of alternating electric currents. By means of such transformation, electric energy can be cheaply conveyed over lines of considerable length, and be utilised in a number of local circuits for lighting and other purposes. The distribution of electrical energy by such means has, however, not succeeded in such a manner as to satisfy the requirements of every-day practice, because it was not possible to increase or diminish the number of points of consumption in operation, without affecting the working of the others in a marked degree, and it was, therefore, necessary to use mechanically acting regulating devices at the different points of consumption, to compensate for the variations caused by the changes in the quality of electrical energy used. In the

Digitized by Google

same manner the efficiency of the systems hitherto used was greatly dependent upon the number of points of consumption in activity.

Now the object of this invention is to make all individual points of consumption of electrical energy quite independent from one another, all necessary regulation being made by or at the generator of electricity. We group the induction coils or transformers so as to constitute secondary distribution stations or local centres. The primary coils of the several transformers of such a local centre may be arranged either in series or in multiple arc circuits. In the former case, the secondary or induced spires of all the transformers of the respective station form a single local circuit irrespective of whether these induced spires are connected up in quantity or in series. In the second case, however, *i.e.*, when the primary coils of the several transformers constituting a local centre are connected up in multiple arc, either each individual induced coil may form a separate secondary circuit, or any number or all of the induced coils of the transformers of a local centre may be connected to form a single local circuit. The apparatus for the actual utilisation of electricity, as incandescent and arc lamps, electromotors, &c., are in all cases connected up in multiple arc in the local secondary circuits.

But the distinctive feature of our system of distribution is, that each group of induction coils or transformers of the several stations of second order shall merely constitute branch circuits of the main line for the primary current, *i.e.*, the primary circuits of the several local centres, any one of these being taken as a whole, are connected in multiple arc. In this manner we have conductors distributing the primary (high tension) current in as many branch circuits as there are local centres, and any desirable number of secondary (low tension) circuits. Now the electromotive forces of the two coils of a transformer bear a constant ratio to one another—Therefore if the internal resistance of such an apparatus is very low, the secondary tension will remain almost unaltered, if we only have a constant difference of potential at the terminals of the primary coil. The



individual points of consumption in the several local circuits are independent of one another by reason of their distribution as branch circuits derived from the secondary line (*i.e.*, connection in multiple arc), provided only that the internal resistance of the transformers be relatively low, and the primary tension at the station invariable. If the independence of individual groups of lamps must be still more perfect, it will be advisable to feed such a group by an independent line, as any desired number of secondary circuits may be derived each separately from one transformer. It follows from the foregoing that our system of distributing electrical energy by means of alternating currents and induction coils or transformers is based upon having a constant difference of potential in the primary conductors as well as in the secondary ones. In a distribution of current, according to our system, there will be a variable intensity of current in the main line as well as in every branch circuit of it, in contradistinction to the systems of distribution by inductional transformers hitherto known or proposed, all of these being based upon constant intensity of the primary current—in our system the intensity of the primary current varies in the same way as the number of points of consumption in activity. This is caused by the counter-electromotive force of the transformers, somewhat increasing when the intensity of the secondary current diminishes, and *vice-versâ*. The consumption of energy for each local station varies in the same manner as the current in the corresponding local circuit, and, consequently, the total consumption of power varies in accordance to the total supply of current in the secondary circuits.

The drawing is a diagram showing the manner in which we supply local centres from the main line. At O is the central station. Between the main lines M and N the tension is invariable. Three local centres or secondary stations are shown. Station I. consists of a single transformer; at Station II. there are two transformers, with their primary as well as their secondary coils connected up in multiple arc; at Station III. there are three transformers, with their primary coils in series, the secondary ones in multiple arc. As it will be seen, all the branch circuits leading to the several local centres are derived as parallel circuits from the main line —*i.e.*, connected up in multiple arc. We desire it distinctly to be understood that the form of the induction apparatus or transformers used may be of any kind whatever, without departing from the principle of our invention.

Having now particularly described and ascertained the nature of the said invention and in what manner the same is to be performed as communicated to me by my foreign correspondent I declare what I claim is:—

In the application of induction coils or transformers for alternating electric currents, the arrangement of several stations of second order as branch circuits of the main line, *i.e.*, connecting up the local centres with the main line in multiple arc, to which main line is supplied an alternating electric current of a tension as constant as possible, substantially as described and shown in the drawing.

Dated this 12th day of December, 1885.

W. P. Thompson, per his Agents, W. P. Thompson and Boult.

[A.D. 1885, April 27, No. 5,201.]

COMPLETE SPECIFICATION.

[Communicated from abroad by Carl Zipernowski, Max Déri, and Otto Titus Bláthy, all of Budapest, in the Empire of Austria, Engineers.]

Improvements in Induction Apparatus for Transforming Electric Currents.

I, Charles Denton Abel, of No. 28, Southampton-buildings, Chancery-lane, in the county of Middlesex, consulting engineer and patent agent, do hereby declare the nature of my invention for "Improvements in induction apparatus for transforming electric currents"; and in what manner the same is to be performed to be particularly described and ascertained in and by the following statement:—

It has been found that induction apparatus hitherto known, namely, Ruhmkorff's apparatus, as well as the newest apparatus of Gaulard and Gibbs are unsuitably constructed. Especially when electric currents of great strength are intended to be transformed by means of such induction coils, it should be the endeavour to obtain as favourable a useful effect as possible, and to produce with the smallest quantity of copper the greatest possible effect, inasmuch as the smaller the applied weight of copper may be, the lower will be the degree of heating, and consequently, also, the loss of strength to be expected.

It has been found that the constructors of the apparatus hitherto in use have in particular made an error in this way that they paid greater attention to the copper wires than to the iron cores, whereas it is believed that the distribution of the iron is the most important factor. All induction apparatus hitherto in use were made in the form of a bobbin with two or more coils, as shown in Fig. 1 of the accompanying drawings. A much better result has already been obtained by my correspondents, by making a ring of insulated iron wires, in a similar manner to the iron armature of a Gramme ring. This ring is surrounded with copper wires as shown in Fig. 2 in such a way that the electric current flows through all the convolutions of the primary wrapping in the same direction, and, therefore, no magnetic poles will be generated in the iron core;—one part of the wire convolutions takes up the inducing current, whilst the other part gives off the induced currents. The induction effect is thus the same in each convolution of the coils, quite in opposition to the induction bobbins hitherto in use, where the effect in the middle wires was a great deal stronger than on the outer parts of the bobbins.

The effect is considerably more favourable in the inverted arrangement, as shown in Fig. 3; two or more bobbins are made of insulated copper-wire and are formed into a ring. Round this ring magnetically insulated iron wire is wound as tightly as possible. From the ring of copper wire two or more ends are taken for conducting the induced current. The mode of connection of the iron wires is quite different.

Figs. 4 and 5 and also Fig. 6 show modifications of such an induction apparatus in which the convolutions of copper wire are enveloped round about with iron wires. In lieu of iron wires, iron plates may also be employed; these plates need not be spirally connected together; they are piled up one over the other like the elements of a dry Voltaic pile with insulating sheets between them. Into the hole stamped out in the middle, and passing through the whole plate column, are introduced the insulated copper wires and suitably connected for induction. In Fig. 5, two plate-columns are represented, and in Fig. 6, four. The number of these columns or bobbins of iron wire may, of course, be increased at will. But the direction of the current in two wires, the columns whereof touch one another, is always inverse.

Fig. 7 shows another construction of these induction apparatus. Iron plates of any optional shape are here employed, a great number of which are piled one over the other, but so that each two plates are separated by an insulating sheet. This plate column is peforated at several places, preferably in such manner that the perforations are identical in all the plates or sheets. In these holes the copper wires are passed to and fro, as shown in the figure—that is to say, in such a way that the current in two parallel contiguous branches of the wire must flow in opposite directions; or the wires may be passed in continuous convolutions. The induction effect of such a plate column upon the wires has then in each branch of the wire the same value, and the several effects thus united give a very high result.

Digitized by Google

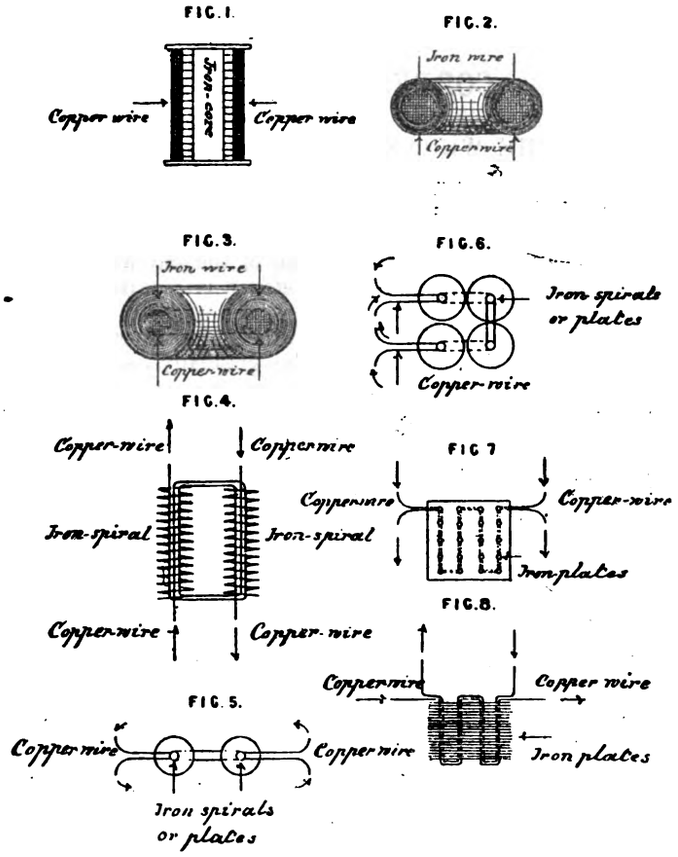
In lieu of employing insulating sheets the plates themselves may be covered with an insulating mass, such as varnish, lac, etc., and then be piled one over the other. It will be evident that the above described method of construction is capable of being modified in a great variety of ways, both as regards the number of coils, the number and shape of the plates and of the conductors which may be either copper wires, bars or tubes.

Having now particularly described and ascertained the nature of my said invention and in what manner the same is to be performed I declare that what I claim is:—

* 1. The construction and use of induction apparatus as herein described with reference to Fig. 2 of the drawings wherein the iron core is formed as an annulus of circular or other shape.

2. The construction and use of induction apparatus as herein described and shown in Figs. 3, 4, 5, and 6 of the drawings wherein the core consists of the inducting and induced copper wires, which are entirely surrounded with magnetically insulated iron wires or magnetically insulated iron plates, the shape being either circular or polygonal, or composed of several columns, as shown in Fig. 6.

3. The construction and use of induction apparatus as herein described and shown in Fig. 7 consisting of magnetically insulated iron plates, which are



Reduced Facsimile of Drawing in Specification.

perforated at several places, with insulated copper wires passing through the perforations disposed either in windings passing to-and-fro or in continuous convolutions.

ABEL and IMRAY, Agents for the Applicant,
28, Southampton-buildings, London, W.C.

Dated this 27th day of April, 1885.

* This first claim was "disclaimed" Oct. 29, 1886.

THE HISSING OF THE ELECTRIC ARC.

The following is an abstract of the conclusion of the discussion which took place at the Institution of Electrical Engineers on April 13th, in connection with Mrs. Ayrton's Paper on this subject:—

Prof. J. A. FLEMING said there were many points in connection with the arc that apparently could only be properly investigated with the guidance of some theory of what was going on in the arc. When one looked at a continuous-current arc the first thing noticed was its want of symmetry, viz., the positive carbon was at a very great temperature, then there was the cooler carbon vapour and then the much cooler negative terminal. Seeing that the phenomenon of the arc consisted in the conduction of the current through a column of vapour, if they asked by what process that was effected, he thought they would be brought to the conclusion to which most investigators who had studied the propagation of currents through gases had been brought. It appeared to be very similar to the electrolysis of liquids. One theory was that it was electrolysis going on in a gaseous column. Starting with that as a provisional hypothesis, he said that in the electrolysis of liquids the chief phenomenon was the fact that the molecules of the liquid were broken up into ions, which were moved in opposite directions, and according to the majority of researches, these ions moved with very different velocities. Accepting this as a provisional hypothesis—that in the arc electrolysis of the carbon vapour was going on by the separation of the two carbon ions, which were being taken in opposite directions rapidly—he suggested that the velocity of the negative ion was much greater than that of the positive ion. The result would be that there would accumulate upon the pole of the positive crater negative ions which would cover up that crater with what he might call a "cushion" of negative carbon ions which would practically have the effect of a resistance. With regard to the behaviour of the arc when air had access, this, as shown by Mrs. Ayrton, produced the phenomenon of hissing. The result then of the access of air or oxygen to the arc was to destroy by combination these negative ions near the crater of the carbon, and that would immediately produce an equivalent diminution in the resistance of the arc. This process would be an intermittent process, because the effect of the diminution of the resistance would be to produce a momentary greater current, and that again would produce a further deposit of the ions. This pointed to the fact that a hissing arc must be an intermittent arc. Since the reading of the Paper, he had examined a hissing arc in a revolving mirror, and had found that a hissing arc *was* an intermittent arc. This had already been noticed by Messrs. Frith and Rogers, and the process going in the normal arc, according to his (Prof. Fleming's) view, would be something of this kind—that the electrolysis taking place in the arc provided the means for the passage of the current, and the rush of these negative ions to the crater was the cause of the excavation of the crater. The arc practically fed itself by this process, which was an easy way of explaining the manner in which the arc had to be started and the necessity, so to speak, of having to begin the process over again when the arc was blown out. In addition, he thought this theory would explain in some way the formation of the mushroom on the negative carbon at the very moment hissing began. It also would explain why it was that the hissing started apparently when oxygen or air had access and not when nitrogen was there; because to have any hissing there must be intermittence, and there must be something to remove this "cushion" of carbon ions. The hissing caused by hydrogen might be explained in this way also, but of course the carbon ions would not be removed by any neutral gas, and he ventured to make the suggestion that any other gas would do that, or any vapour, which had the property of combining with carbon at a high temperature. Perhaps Mrs. Ayrton might say she had tried it, but that it had failed; but he would then suggest that it might be well to use chlorine, iodine or any similar gas. Mrs. Ayrton had not, in her Paper, entered into the discussion of such points as the negative resistance and counter electromotive force which belonged to the region of hypothesis. With regard to the question of counter E.M.F. he had long held the opinion that there was no such thing as counter E.M.F.

Captain W. DE W. ABNEY thought that anyone who had worked with the electric arc could not but agree that the conclusions and deductions made by Mrs. Ayrton were perfectly right. The phenomenon of the hissing of the electric arc had long been of interest—and very sad interest—to him, because it had interfered many times with experiments he had in hand, and it was by rule of thumb that he had come to the conclusion that a certain voltage was requisite, and so on. Long before Mr. Trotter brought forward his interpretation of the arc, he (the speaker) had been considerably bothered by the hissing, in his experiments. He threw an image of the carbon points on the slit of a spectroscope, having passed it through the prisms and fixed it on a focussing screen. He then removed the focussing screen and once more recombined the spectrum, and formed an image of the prism upon a distant screen and by that means got any colours he wished to investigate. In a great number of cases it had happened that the patch of light so formed had given him the impression that it was oscillated, but he had found afterwards that there was a distinct rotation of something in the arc light. To investigate this still further, the slit of the spectroscope was diminished to a pin-hole, and this exemplified the whole phenomenon on the screen, for by using a pin-hole he got an image of the carbon points on the prism. He hesitated to say whether the rotation was as much as 450 times a second or minute, whatever the case might be, but he could say that, immediately before the hissing, there was seen the phenomenon which Mrs. Ayrton had described so well in her Paper. It was not so quick, however, and this fact led him to the conclusion that perhaps it might be due to oscillation in the arc as Prof. Fleming had pointed out. He had not investigated this, but at the same time the phenomenon of hissing was certainly accompanied most frequently with a rotation, but not always. He thought Mrs. Ayrton would be rewarded if she made the following experiment, viz., throw a monochromatic image of the electric light on a screen and watch it. This was done in a very easy way by throwing an image of the carbon points by means of a lens through a slit. Instead of having a slit without a lens, put a lens quite close to the slit and throw a sharp image upon the prism. Then take away the lens and she would get an image in white light of the carbon points on the screen. Then if she put a slit in the focus of the spectrum and passed it through, she would get an image of the carbon points in every colour, and it was very interesting to find the spot where the flame came on the screen when the hissing began. There was a certain phenomenon which began when the hissing began, viz., the flame surrounding the carbon points was quite different to the violet spectrum which was ordinarily seen between the poles. This was of a yellow colour and was probably a higher compound

Digitized by Google

of carbon and oxygen. It also appeared immediately before the hissing, but not very readily.

Prof. W. E. AYRTON said that at the beginning of the discussion Prof. Thompson criticised a statement that he had made on a previous occasion. His statement was that if they were dealing with normal arcs and kept the potential difference between the carbons constant, then when the carbons were drawn apart slowly so as to lengthen the arc, they increased and not diminished the current, as might, *a priori*, have been expected. To this statement Prof. Thompson had taken exception, and had said that what should have been stated was this, that with normal arcs if they lengthened them and wished to keep the potential difference between the carbons constant it was necessary to alter the outside conditions so as to increase the current. This appeared to him to be a distinction without a difference. Supposing they had two arcs of different length with the same carbons, and they wished the potential difference to be the same, say 55 volts. With a 4mm. arc they would have some 7 amperes, and with a 5mm. arc 11 amperes. There were millions of outside conditions which enabled them to have these 55 volts, and there were millions of other outside conditions which would enable them to have the same potential difference with a longer arc. If they had the two together they must select outside conditions, which would enable them to have 55 volts in both cases; exactly the same thing applied to a wire resistance. Another criticism of Prof. Thompson's was with reference to what Capt. Abney had referred to, viz., the slow rotation of the bands, which may be seen on the crater before the arc hisses. Prof. Thompson said that Mr. Trotter had pointed this out previously. The curious part about it was that in Mr. Trotter's Paper before the Royal Society, and in the account given by Mr. Trotter in *The Electrician* (of which he was then editor), there was no reference whatever to this slow rotation.

Prof. S. P. THOMPSON here interposed to the effect that what he said was that Mr. Trotter had shown it to him and that it was referred to in his (Prof. Thompson's) Cantor lectures.

Prof. W. E. AYRTON then intimated that he was glad to hear this, but that it was curious, if this phenomenon was commonly known of, that an area of the crater should have been suggested (he believed even by Dr. Thompson himself) as a standard of light.

Prof. S. P. THOMPSON replied to the effect that that was quite true, but that he had abandoned his idea when Mr. Trotter showed him the phenomenon of rotation.

Prof. W. E. AYRTON then continued saying that Mr. Trotter had been kind enough to ask him to go to his house and see the rapid rotation, which could only be seen in the rotating sectors, and he had no recollection whatever of Mr. Trotter having drawn his attention to the slow movement of the dark bands which could be seen without any sectors at all. He did not think that Prof. Thompson quite grasped last time what Mrs. Ayrton meant about that region of instability between the silent and the hissing states. This was really quite distinct from what Prof. Thompson had referred to, and from what he (Prof. Ayrton) had referred to, viz., whether the length of the arc was altered. What Mrs. Ayrton was putting forward in her Paper was what happens when the length of the arc was not altered.

Mrs. AYRTON thanked all those who had criticised her Paper for the very kindly manner in which they had done it, and everyone for the extremely warm way in which they had welcomed her Paper. Prof. Thompson had asked her what she meant by the hissing arc; did she mean a green arc, or an arc in which the P.D. had fallen, or an arc that was making a noise? An arc made a great many noises. It hissed in all sorts of ways and under all conditions. There was the long arc with small current which made a noise like a kettle just beginning to boil, and there were arcs under other conditions of which she did not even know, and which made all sorts of noises. But there was only one hissing arc as she knew it, viz., the arc in which the potential difference fell. The interesting part of the subject to her was the diminution of the potential difference between the terminals of the carbons. That seemed to her the most interesting of all the phenomena attached to it, and it was upon this that she stood or fell. The green colour she believed to be intimately connected with the fall of potential, but she could not say how. Mr. Mordey had asked if the hissing arc gave out less light. She believed it did, but it was difficult to say. Did he mean less light for the power supplied? M. Blondel in 1893, in a Paper written in *The Electrician*, said that the hissing arc always gave 10 per cent. or 20 per cent. less light than the normal arc. But how much light did the normal arc give? If they have different currents they had different light. It was true that the arc appeared duller when it began to hiss, but she had found that the power supplied to a hissing arc was less than the power supplied when the arc was silent; and therefore it was very difficult to say whether, for the amount of power supplied, the amount of light given out was less when the arc was hissing than when silent. As regards arcs being unsteady when hissing, that was only the case when the arc was only just at the hissing point. Everyone who had studied them must know that it was possible to get an extremely steady light from a hissing arc. As to the dark band of the alternate current arc, referred to by Mr. Mordey, she had no notion of this, as she had never worked with alternate current arcs. She had had various letters sent her about her Paper, and one of these letters had suggested that the ends of carbons shown by her at the reading of the Paper were of a very different character to those he was accustomed to with the ordinary enclosed arc. She thought she had made it clear that she was using an ordinary enclosed arc enclosed in a crucible arranged in such a way that the air could be let in in different quantities or entirely excluded. Her arc, however, was never completely enclosed because there was always sufficient clearance between the positive carbon and the crucible to allow a certain amount of the vapour inside to escape, but not sufficient to allow air to get in. M. Blondel had written to her and mentioned that he had noticed the green shade in the arc in 1893. They all knew M. Blondel's work, and they must respect his opinions because he had done more good work on the arc than any other single individual. In this letter he had reminded her that she had not mentioned the opacity of the vapour of the hissing arc. This, she said, was certainly more opaque than the open arc, but not so opaque as the enclosed arc. M. Blondel had also suggested that this opacity was caused by the carbon being disruptive. In a part of this letter from M. Blondel, which Mrs. Ayrton read, he stated that his opinion was that hissing was caused by particles being torn off the positive carbon and dropping on the negative carbon. This Mrs. Ayrton did not think to be the case, as she did not believe the potential difference was sufficient to allow of this tearing off. At the same time she was not prepared to say how the oxygen did act. She was sorry to say she had not properly followed Prof. Fleming's remarks. Why were the negative ions supposed to go more quickly than the positive ones? The mushroom, she mentioned, only took place with a short hissing arc. With regard to the rotation of the arc, she was sure nobody could have studied it from the point of view of light without having seen this rotation.

The PRESIDENT, in proposing a vote of thanks to Mrs. Ayrton, thought they were all the more indebted to her for communicating this most valuable Paper, as she was not a member of the Institution. The fact that they did not now number any lady members amongst them would not debar ladies from becoming members, and he looked forward to Mrs. Ayrton becoming one.

THE WEHNELT INTERRUPTER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Noticing considerable discussion of the Wehnelt interrupter, and its properties and actions, I think I may add a few words as to the probable cause of the actions, with an explanation of why it is that inductance is required in the circuit in order that the interrupter works.

On closing the circuit through the interrupter with an inductance in series, the current value gradually rises until at some point the electrolytic action on the surface of the platinum anode gives rise to bubbles of gas, which diminish to some extent the surface of the platinum in contact with the liquid. On account of the inductance in circuit there arises out of this condition a critical state which causes the instant stripping of the liquid from the platinum—an explosive interruption, so to speak. The inductance in circuit tends to keep the current flow constant, *i.e.*, it prevents the current falling off as the surface of liquid in contact with the platinum falls off.

There results from this, on the beginning of the uncovering of the platinum by the liquid, a state of unstable equilibrium, whereby the current tending to flow at one value is crowded, so to speak, into a section of liquid which from the moment it begins to diminish around the platinum must immediately continue up to complete interruption. This sudden interruption cannot occur without greatly increased voltage across the terminals of the interrupter, and necessarily between the platinum anode and the liquid which is being separated. This forces a discharge through the last portions of the liquid in contact with the platinum, and results also in a vigorous driving off of the liquid, together with the possible dissociation of a portion of the liquid. The platinum surface also becomes pitted and worn by continued use, owing to the violence of the discharges attended with spark. The platinum anode would naturally be surrounded by oxygen gas and, perhaps, in addition thereto, water vapour and dissociated water. On the entire cessation of current the water vapour condenses, and the products of dissociation probably recombine suddenly, casting out the excess of oxygen and renewing the condition as at first.

This theory of the action is rendered all the more probable by the fact that the ohmic resistance at the contact of the platinum and the liquid must necessarily be high, on account of the restricted section; and that, on the beginning of separation by gas bubbles, this resistance must instantly rise, the current, owing to the inductance in circuit, tending to remain of the same value as before, causing a critically increased drop of potential over the platinum liquid contact, and, in consequence, a critically increased energy delivered thereat. This view of the actions was arrived at when working with the interrupter, and in studying its properties.

—Yours, &c.,

ELIHU THOMSON.

A CORRECTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have noticed a slight mistake in my letter with reference to the Wehnelt interrupter, which you published in your issue of the 7th inst. In comparing the glow produced on a fluorescent screen by an X-ray tube excited by an 18in. coil with the new interrupter, I stated that the glow was as brilliant as that produced when the tube was excited by means of a 160-plate Wimshurst machine, instead of by a "16-plate machine," as you printed. I draw attention to this, because I believe that this 160-plate machine is the largest that has yet been made, and gives extraordinarily fine X-ray effects.—Yours, &c., E. W. MARCHANT.

Blythswood Laboratory, Renfrew, N.B., April 19, 1899.

THE THEORY OF THE MARCONI TELEGRAPH.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Although several theories on the laws which govern the function of the vertical wires and the earth or capacity connection in Mr. Marconi's system have been advanced none would seem to have met with general acceptance. I am therefore induced to submit through your columns some observations which may tend to elucidate the part played by these adjuncts in wireless telegraphy. To take, firstly, the question of the vertical wires. Might we not reason that these wires, when charged, act *inductively* upon one another through stress in the intervening ether, just as the one plate or coating of a Leyden jar when charged induces a charge in the other coating owing to stress in the glass insulating medium which separates them? In short, may we not suppose that the vertical wire attached to the upper sphere of the transmitter is charged to the potential of the spark each time the key circuit is closed, and this induces effects in the distant vertical wire and coherer? If we can justly regard the action as being inductive pure and simple we need seek no further for an explanation of the important effect of these vertical wires in increasing the signalling limits.

At first sight it appears extraordinary that any such inductive action should take place over distances amounting to many miles. We must, however, bear in mind the frequency and high potential of the spark, and also the extreme delicacy of the coherer. It seems only reasonable to suppose that, as currents of high frequency overcome resistance, so *inductive distance* is increased by the same effect.

The inductive hypothesis explains intelligibly, I think, the fact that better results are obtained with vertical conductors than with horizontal conductors, because the vertical conductor gives greater elevation; and the earth and points of intervening capacity then absorb less of the inductive energy, radiated in the form of rapidly succeeding waves from wire to wire, than is the case when the conductors are horizontal or in any other position. This absorption effect would seem to explain why greater distances have been spanned at sea than on land, the surface of the sea offering no points of elevated capacity to intercept the inductive rays.

There remains for consideration the function performed in this system by the earth connection used for the transmitter and coherer respectively. I would submit that this function is to discharge the vertical wires after each signal, the one through the secondary wire of the induction coil and the other through the circuit of the distant relay, which, when the coherer is passive, offers a path to earth after each impulse.

In the discussion on Mr. Marconi's Paper it transpired that the earth on the coherer may in certain cases be severed without interrupting communication or even affecting the reception of signals. In these cases it would appear that the *surface leakage* of wire and pole, together with the capacity and leakage of the relay system itself, are in themselves equivalent to an earth, bearing in mind the very low capacity of the elevated conductors and the necessarily very small impulses which they attract. Apparently it is owing to its higher potential or inductive energy that the transmitter requires a better earth than suffices for the receiver.

Information on these points will doubtless be forthcoming from authorities on the subject. In the meantime these observations are with diffidence offered to your readers.—Yours, &c., H. W. SULLIVAN.

[The publication of the above has been delayed until this issue, at Mr. Sullivan's request.—ED. *E.*]

ELECTRICAL MOTOR CARRIAGES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There seem to be so many obstacles to the ultimate firm establishment, and apparently inseparable from the early life of a new industry, such as the adverse state of the law, the over-sanguine inventor, and lastly the professional company promoter, that those who are most interested in the matter, and one who has largely contributed to the years of labour necessary in making the electrical vehicles a practical success, take all these things as a matter of course. But when a gentleman of the standing of Sir David Salomons states (assuming that he has been correctly reported in the *Royal Magazine* of this month) that the electrically propelled carriage is an impossibility, it is to be pardoned if the remark is not allowed to pass unchallenged. And one is almost inclined to think that it was made without due consideration, as was the case when the same gentleman, in estimating the cost of propulsion by electricity a year or so ago, based his calculations on the cost of electric current at 4d. per unit, whereas at that very time it was to be obtained in London at 1d. per unit!

That one does not see many self-propelled carriages on the streets here is not evidence that they are unpractical. Our natural caution in adopting new ideas and our love of horses are enough to account for this; although, as a lover of horses myself, one of the last uses I would put a horse to would be the hauling of a tram car or an omnibus, and I think that many of the horses one sees in cabs are fit subjects for anyone's compassion, and the sooner their use is rendered unnecessary by the introduction of electricity the better.

In spite of the long start which the automobile movement has had on the Continent, and in view of the fact that it is only during the last two years or so that one was allowed to run a motor vehicle on the street here at all, it is a very significant fact that the principal systems of electrical vehicles which have been adopted in Paris are of English origin.

The argument, which Sir David is reported to have used when discussing the "inutility" (*sic*) of electrical motors, "it is as if one should go for a fast drive and expect the horses to gallop along with a load of passengers as well as a dozen sacks of coal," is not to the point, and one is tempted to remark that the horses would go very fast indeed if they had no load at all to carry. But why Sir David should try to prove the matter by wishing to carry accumulators (represented by the sacks of coal) in a horse-drawn vehicle, I fail to understand, for when we carry a set of accumulators in our electrical vehicle we do not want to carry a horse, but do without them.

In conclusion, I can only say that, regarding the weight of an electrical carriage, it is now quite possible to produce one capable of carrying two persons for a 40 mile journey, the total weight of the carriage being under 12 cwt., at a cost for electric current of two shillings (2s.) and an annual expense for renewal of accumulators of £20.

Thanking you for your courtesy in inserting this letter and apologising for taking up so much of your valuable space.—Yours, &c., C. OPPERMANN.

The Automobile Club, S.W., April 17, 1899.

Wiring Rules.—The number of the *Journal* of the Institution of Electrical Engineers, just issued, contains the conclusion of the discussion on Wiring Rules, as well as the proceedings at ordinary meetings up to the conclusion of the discussion on Prof. Wilson's Paper. No less than eight members have communicated their share of the Wiring Rules discussion in writing, Mr. Pigg has communicated his reply, and Mr. Wordingham has added about a page to his remarks.

PARLIAMENTARY INTELLIGENCE.

NORTH-WEST LONDON RAILWAY BILL.

Last week the Select Committee of the House of Commons, of which Mr. Jeffreys is Chairman, the other members being Mr. Souttar, Mr. Bathurst and Mr. Shaw, commenced the consideration of the North-West London Railway Bill, under which authority is sought for the construction of underground electric railways, connecting the Marble Arch with Cricklewood. Mr. Balfour Browne, Q.C., Mr. Joseph Shaw and Mr. Hutchinson appeared for the promoters; the only opponents, the London County Council, were represented by Mr. Freeman, Q.C.

Mr. BALFOUR BROWNE said the line would be four miles long, and it was supported by all the local authorities through whose districts it passed. A railway was under construction along the Bayswater-road, past the Marble Arch to the City, and it was proposed to connect the two railways at the Marble Arch. The stations on the new line would be at the Marble Arch, at Edgware-road (near the Metropolitan Railway Station, with which it was to be connected), at Hall-road, Maida Vale, at Kilburn, at Brondesbury, another a little further to the North, and then the terminus at Cricklewood. The line would also be connected with the Baker-street and Waterloo line now under consideration. The large extent of the traffic on the proposed route was indicated by the fact that there were some 6,000 omnibuses plying daily. The time occupied on the journey from Cricklewood to the Marble Arch by omnibus was about 40 minutes, but by the railway it would be only half that time. The capital asked was £1,500,000, with borrowing powers of £500,000; and the line, which was to consist of double tunnels, it was estimated would cost £10,65,183. Each train would carry 350 persons, and each lift at the stations would accommodate about 250 persons. The opposition of the County Council was designed to place on the Company a clause under which they would have to carry workmen at an unremunerative rate and at an hour of the day which the company held was unsuitable for workmen's trains, and which would allow a large number of clerks and others well able to pay ordinary fares to travel by the cheap trains. The Company desired to provide workmen's trains, but only at a proper time and at a remunerative rate. If the clause of the County Council were adopted it would mean that they would be unable to raise their capital.

Mr. BRAITHWAITE, of Messrs. Foster and Braithwaite, stockbrokers, of Austinfriars, and Mr. C. C. Macrae, vice-Chairman and Managing Director of the Railway Share Trust and the Railway Debenture Trust, and a Director of the London, Brighton and South Coast Railway, gave evidence showing that if the clause of the County Council were put upon them they would be hampered in raising the capital.

Sir HENRY OAKLEY, formerly general manager of the Great Northern Railway Co., and Chairman of the Central London Railway Co., gave evidence showing the large traffic on the route of the line, and said that the locality of Cricklewood was very ripe for development, and would develop largely if increased facilities were given. Assuming the working expenses to amount to 50 per cent., the line would yield a minimum, he estimated, of 3 per cent. He thought, however, the expenses ought to be less than that, because with an electric railway there was not the same increase of expense, train by train, as with an ordinary steam locomotive. They might fairly and reasonably estimate the expenses at about 40 per cent; but whether the expenses were 40 or 50 per cent., having regard to the enormous traffic at present existing, and the prospects of development, he had no doubt the line would be a dividend earning one. He deprecated the passing of special legislation in the case of each railway with regard to workmen's trains. There was an Act under which the question of accommodation of workmen was referred to the Board of Trade or the Railway Commissioners, and he thought that course should be adopted in the present as in all cases, and not that the matter should be dealt with and settled specially, in each individual case.

Sir BENJAMIN BAKER, joint-engineer with Sir Douglas Fox for the proposed line, said the estimates, &c., were all based on his experience in connection with other similar lines in London. The estimates worked out to about £450,000 per mile, showing that the line would be very expensive.

A long discussion arose round the demands of the London County Council for lower workmen's fares than those proposed in the Bill, but the Committee came to the unanimous decision to allow the return fare of 2½d., the single fare 1½d., the intermediate 1½d., and the hour of arrival from 8 o'clock.

The Bill was then ordered to be reported to the House.

BAKER-STREET AND WATERLOO RAILWAY BILL.

On Tuesday a Select Committee of the House of Commons, presided over by Mr. Jeffreys, commenced consideration of the Baker-street and Waterloo Railway Bill. The counsel engaged for the Bill were Mr. Pember Q.C., Mr. Ernest Page, Q.C., Mr. W. J. Noble, and Mr. Joseph Shaw. There were a considerable number of petitions in opposition, including those of the Metropolitan Railway Co., the Charing Cross, Euston and Hampstead Railway Co., the Grand Junction Canal Co., the Gordon Hotels Co., and the London County Council.

Mr. PAGE said under the Bill power was sought to make extensions of a railway authorised in 1893, and to provide for an extension of the time granted for the completion of that line. By a later Act power was given, in consequence of the known intention of the Great Central Railway Co. to make their London terminus at Marylebone, for the Baker-street and Waterloo Co. to extend their line to Harewood-square for the purpose of communicating with the Great Central terminus. The extensions now proposed were from Harewood-square to Paddington station and from Portland-road to Euston. It was proposed that there should be two subways, one at Paddington and another at Trafalgar-square from the underground station there, reaching the surface at the corner by the Grand Hotel. The London and Globe Financial Co., of which the Marquis of Dufferin was chairman, were promoting the line, and as that Company had already spent £300,000 on it there was little doubt that the line—whether the public subscribed to it or not—would be constructed. The length would be about 2⅛ miles, and the estimated cost was £856,000. The capital powers sought were for £1,400,000, the balance being required for the subways, rolling stock, and the erection and equipment of a generating station in South London, where sufficient electricity to work the whole of the line would be generated. The petitions of the Metropolitan and Charing Cross, Euston and Hampstead Railway Companies alleged that the line would compete with them. The Grand Junction Canal Company's opposition was based on the suggestion that danger would result to their canal by the passing of the line for some length under it. The County Council opposed the Bill with a view to imposing on the Company some special liability with regard to cheap trains for workmen. Counsel pointed out that in this matter the Company was in a very different position from the great trunk lines, and contended that the general law was sufficient to meet the case.

Much evidence was given in favour of the proposals to extend the line to connect with Euston and Paddington by Mr. Harrison, General Manager of the London and North-Western Railway Co., Mr. Wilkinson, General Manager of the Great Western Railway Co., and Mr. William Pollitt, General Manager of the Great Central Railway Co. and Mr. Owen, General Manager of the London and South-Western Railway Co. These witnesses were unanimous in their opinion that the projected line would be of enormous advantage to persons travelling to London over their systems, and desiring to go to Waterloo or to the great shopping centres of Regent-street and Oxford-street; and to the extent that the line was used the traffic through the streets would be relieved. Mr. Owen stated that the traffic to and from Waterloo was increasing at an almost phenomenal rate, the passengers booked to and from the station having grown from 18 millions in 1888 to 28 millions in 1898. Of these a very large proportion went to the City and the remainder to the West. He had always considered the lack of communication between the great termini of London as one of the great faults of our railway system, and any proposal to link up two or three of the termini at present without communication, he would heartily support. His experience of the Waterloo and City Railway enabled him to say that the public very much appreciated the mode of conveyance contemplated by the Bill, the number of passengers carried on that line in the last 4½ months having been 1½ millions, which would have been much larger if the Company had had more rolling stock. In reply to the Chairman, he said the ventilation on the Waterloo and City line was absolutely perfect. It was simply caused by the trains in their movements drawing after them a large current of air.

Sir BENJAMIN BAKER (one of the engineers to the line) was examined at length regarding the proposals of the Bill. He said the site of the generating station was originally placed in Paddington, but, owing to the opposition with which the scheme was met, another site south of the Thames was fixed upon. There would be a covered-in underground depôt at Paddington, where carriages would be stored, light repairs executed, &c. The machinery necessary for the repairs would be driven by electricity. Probably the traffic from Charing Cross to Paddington would be heavier than that from Paddington to Waterloo. They proposed to run trains each six minutes from Euston and Paddington, which would give them a three minutes' service to Waterloo. Though an Act was obtained in 1893, no works had been done till about a year ago. The £300,000 spent had been expended principally in the purchase of land. The tunnels and carriages would be the same size as on the Central London Railway, and six inches larger than those on the City and South London line. The tunnels would be constructed in the clay, at an average depth of 60ft. from the surface. His estimates were not excessive, and he had given them as the result of his experience. In his opinion the only way of meeting the congestion of traffic in the crowded thoroughfares was by means of these expensive electric railways. There could be no comparison between the slight disturbance occasioned by them to the inconvenience caused by strings of omnibuses.

The CHAIRMAN: Can you make it quite clear to the Committee how much per mile the railway is going to cost?—The estimated cost of the Baker-street and Waterloo Railway is £575,000 per mile. The cost of the Central London line is estimated at £585,000; the Great Northern and City at £652,000; the North-West London, £435,000; and the Great Northern and Strand, £502,000.

The CHAIRMAN: According to these figures, your estimate is about an average. Does the £575,000 include all contingencies?—Yes, all contingencies, including the electric lifts at the stations (which were not in the original estimates), professional charges and working capital.

Continuing, witness said they proposed to ventilate the line by the shafts at the stations, which experience has proved was sufficient; but, if necessary, they could employ electric fans.

The CHAIRMAN: But if there were a stoppage in the tunnel? We are told that the train in motion causes the ventilation.—I went very carefully into that, for there was some alarm in consequence of the stoppage on the City and Waterloo Railway. It was said that the passengers broke the windows of the carriages. As a matter of fact, they were not in danger of suffocation, but got very hot in consequence of being penned up in the carriages with the windows closed. From calculations made, it is found that if a train were full of passengers in the tunnel, and both ends of the tunnel were blocked up, the passengers might die of starvation, but they would feel no inconvenience from the air.

Mr. W. R. GALBRAITH, civil engineer, joint engineer of the Waterloo and City Railway, and of the Baker-street and Waterloo Railway, confirmed generally the evidence of Sir Benjamin Baker with reference to the

Digitized by Google

Waterloo station. The railway was laid out in 1893 so as to secure an interchange of traffic between it and the Waterloo and City line. The South-Western Company contemplated making another line to Clapham Junction, so they could not secure the land originally fixed upon. They were compelled, therefore, to go to Paddington to secure a site for their sidings and shops.

Yesterday Lord Loch and Mr. Galbraith were re-examined, and the case for the promoters was closed, and the proceedings were adjourned.

GREAT NORTHERN AND STRAND RAILWAY BILL.

This Bill came before a Select Committee of the House of Commons on Thursday last. The members of the Committee were :—Mr. A. H. Brown (chairman), Mr. Leuty, Lord H. Bentinck, and Sir T. J. Gibson-Carmichael.

Mr. Balfour Browne, Q.C., Mr. Fitzgerald, Q.C., and Lord R. Cecil appeared for the promoters ; Mr. Freeman, Q.C., represented the London Council Council, and counsel also appeared for the numerous opponents of the measure.

Mr. FREEMAN, Q.C., said that as the proposed railway was to be underground throughout, and as it was intended that it should run under the new street proposed to be constructed from Holborn to the Strand under the London Improvements Bill, which stood to be next considered by the Committee, he thought the best course would be to take the railway measure independently, but to reserve the decision upon it until the next measure had been disposed of.

Mr. BALFOUR BROWNE said the Railway Bill would in no way be prejudicial to the new street. The present scheme was one of the most important in its bearing on London traffic that had been promoted for a long time. It was proposed to construct an underground railway from Wood Green to St. Clement's Danes, in the Strand. The line would consist of four separate railways, one of which would leave the Great Northern at Wood Green and run to Finsbury Park, and would be about 2½ miles in length. A second railway would begin at Finsbury Park and extend to King's Cross, and would be underground throughout, and be worked by electricity. It would also run almost entirely under the Great Northern line. These lines would not form a portion of the Great Northern Railway, but would be affiliated with it. Although, as the Great Northern were not opposing, the Company would not have to pay for the land in getting to King's Cross, yet they would incur great expense in constructing the tunnels of sufficient strength to bear the traffic of the Great Northern Railway. From King's Cross it was proposed to run the line under private property at a great depth, and to pay for the necessary easements, a procedure which had been favourably reported upon by a Committee in 1892. From the Central London Railway in Holborn the proposed railway would proceed *via* the new street to be built by the County Council, upon the making of which they were to some extent dependent in order to reach the Strand. The railways altogether would be 6 miles 27 chains in length, and their estimated cost was £2,297,903. It was proposed to fix the Company's capital at £2,400,000, with a borrowing power of £800,000, making altogether £3,200,000. The expenditure per mile, as estimated, would be a low one, viz., £381,000.

Sir H. OAKLEY, formerly Manager of the Great Northern Railway, said he was of opinion that the traffic on the railway would be from 12,000,000 to 13,000,000 passengers per annum. As to the objection of the County Council, the subsoil of a street was of no value to anybody. It would be in the interest of the public to give the promoters the facilities they asked for ; indeed, he should have thought that the County Council would have been glad to see the railway run under their new street.

Mr. CHAS. STEEL, General Manager of the Great Northern Railway, said that his Company were favourable to the Bill. He estimated that the proposed railway would relieve the Wood Green traffic to the extent of between 6,000,000 and 7,000,000 passengers a year. It would save them 30 or 40 trains per day, and enable them to give a better service to outlying districts. If the new street to the Strand were not made the southern portion of the proposed railway would fall with it.

Mr. FREEMAN addressed the Committee for the London County Council. He did not deny that the railway would be a public advantage, but contended that his clients should retain possession of the subsoil of their proposed new street, which they were buying with hard cash. He asked the Committee not to decide the Strand part of the scheme until the London Improvements Bill had been considered.

The Committee ultimately passed the preamble of the Bill. Clauses will be considered to-day (Friday).

Sixty Thousand Words an Hour Telegraphy.—The *Daily Chronicle's* Vienna Correspondent has announced that a Vienna engineer named Pollak has invented "a simple apparatus" capable of transmitting telegraph messages at the rate of 60,000 words an hour. He states that the United Electrical Joint Stock Co. have bought the invention, and that their trials have, up to the present, met with great success; also that experiments will be attempted between Vienna and Budapest next week, and that the company will shortly open up negotiations with all European and American post offices for the sale of the patent. A *simple* apparatus which can transmit and receive at the rate of 1,000 words a minute would indeed be a boon, but we prefer to reserve our opinion as to the possibility of such a feat being accomplished on an ordinary telegraph wire until further particulars of the invention are to hand.

LEGAL INTELLIGENCE.

Castner-Kellner Alkali Co. (Limited) v. Commercial Development Corporation (Limited).

In our last issue we gave the summing up of the Master of the Rolls in this appeal action. It will be remembered that Lord Justice Rigby concurred with the Master of the Rolls in giving judgment for the defendants. Lord Justice Vaughan Williams differed from his colleagues. The judgments of Lord Justice Rigby in favour of defendants and Lord Justice Vaughan Williams in favour of the plaintiffs are given below :—

Lord Justice RIGBY said he proposed, in his judgment, to deal exclusively with the question of the validity of the patent sued upon—Kellner's of 1894. If as, in his opinion, was the case that patent could be shown to be invalid it would be an academic question, whether, on the supposition of its being valid, there would be an infringement, and he did not propose to enter into the question at all. The grounds alleged for holding the patent invalid were disconformity and want of subject matter. He should deal mainly with the first of these, which depended upon the comparison of the provisional and complete specifications according to the true construction of each. This construction was entirely for the Court. Experts, however eminent, had nothing whatever to do with it, though their evidence might be valuable in explaining the meaning of technical terms, the state of the invention and the date of the patent and the working of the apparatus described. The main point for consideration would be the meaning of the words "stationary mercury cathode" which, paraphrased, meant a stationary cathode composed of mercury, otherwise a stationary mercurial cathode or a cathode composed of stationary mercury. He had come to the conclusion that the first was the true meaning differing in this respect from Mr. Justice Bigham, who adopted the second. The difference was crucial, because the second meaning was the only one which rendered it possible, however difficult, to take the further steps which Mr. Justice Bigham had taken for interpretiug in a manner different from its ordinary meaning, what his Lordship took to be "stationary" in reference to surrounding unmoving objects, and he attributed to it a very different and exceptional meaning of "stationary" with reference to the containing vessel. In his judgment it was not only startling, but quite inadmissible, to say that the ultimate development of an invention, which must rely for its validity upon an inventive departure from a pre-existing state of things, would be to bring them back to precisely that pre-existing state of things, as was done by the claim in Figs. 7 and 8 of Kellner, when the bottom of the chamber was rotated. His conclusion was that the actual modification of apparatus exactly described and claimed in Figs. 7 and 8 ; at any rate, when the bottom containing chamber was made to revolve under the cells rigidly connected with one another was not a legitimate development of the invention, the nature of which it was shown by the provisional specification, and that the patent was, therefore, void for disconformity. That was the main ground of his decision as to the invalidity of the patent. Going to the question of subject-matter, even if it could be shown that the objection of disconformity failed, there would remain that of want of subject-matter. Comparing Figs. 7 and 8 of Kellner's with Fig. 1 of Castner's patent, they found in that modification of 7 and 8, viz., the motion with which the cells remained still and the bottom alone was made to rotate, an exact correspondence between Castner and Kellner up to the point where the question arose how to move the mercury cathode. Castner effected this by a stirrer consisting of helical blades mounted on a rotating shaft passing down the apparatus. All that Kellner did was to substitute for this rotating stirrer a rotation of the bottom of the vessel containing mercury. There was no clear evidence of any advantage over Castner in this arrangement. Further, the modification introduced by Figs. 7 and 8, by moving the bottom of the vessel, so far from being shown to be an important improvement in practice from former apparatus, had never been used at all, and there was no evidence of experience, or even experiment, that it would practically work at all as a commercial success. In his judgment the Kellner patent was void from want of subject-matter, so far as concerned the particular modification of apparatus which had been dealt with and the claim (No. 3) founded thereon ; and, therefore, the whole patent was void on this ground also.

Lord Justice VAUGHAN WILLIAMS said he differed from the other members of the Court, and as he did not think the Kellner patent was bad for disconformity he should necessarily have to go into the whole question, both of the merits of the Kellner patent and of the alleged infringement of the Kellner patent by the Rhodin patent. In order to deal with the case it was necessary to make some comparison of the plaintiffs' patent and prior letters patent, and in particular a prior patent taken out by Castner. The main features of the Castner patent seemed to have been :—(1) A single chamber divided into two sections—one for salt and water, and one for pure water—by a partition not extending quite to the bottom of the vessel, and sealed by the mercury at the bottom of the vessel. (2) A continuous electric current passing through both chambers. (3) The adjustment of the proportion of amperes passing through the chambers respectively by a division of the continuous current. (4) The change in the location of the mercury relatively to the two chambers by the flow of the mercury round and round the containing vessel, produced by the propulsion of paddles attached to a central revolving shaft. (5) The maintenance of an average minimum of 0·2 per cent. of sodium throughout the mercury by the churning produced by the propelling paddles. The idea of Kellner seemed to have been this : He had a large dish with mercury at the bottom. On the top of this mercury he had movable cells with the lower edge just dipping into the mercury so as to seal the bottom of the cell and prevent any liquid which might be placed inside the cell running out at the

Digitized by Google

bottom. These cells he filled with salt and water. The whole of the vessel outside these cells he filled with pure water, so that the whole of the mercury which was not covered by the salt and water contained in the movable cells was covered with pure water; he electrolised the salt and water by a current passed through the salt and water to the cathode formed by the mercury. This current was not continuous, and did not as in the case of Castner's patent pass on through the pure water. He then by shifting the bells containing the salt and water electrolyte about on the surface of the mercury caused patches of the mercury to be alternately covered by the salt and water electrolyte and the pure water respectively, thus charging with sodium the patch of mercury covered by the salt and water electrolyte, and discharging of sodium the same patch of mercury when subjected to the pure water by the shifting on of the cell containing the salt and water to the adjoining patch, which prior to the shifting had been covered with salt and water. In order that the shifting of the cells should not by reason of the dipping of the lower edge or lips of the cell into the mercury, carry with it the patch of mercury which was under the cell at the time of the shifting of the cell, Kellner made in the lower edge of the cell a series of notches, or openings or serrations. The mercury in Kellner's apparatus had no fluid motion, or, at least, was intended to have none relatively to the vessel containing it. The Kellner apparatus had no continuous electric fluid, not even an adjusted continuous current passing through the pure water cell. In Kellner's provisional specification the motion of the cell containing the salt and water electrolyte was a to-and-fro motion. In the complete specification he made several additions, which his counsel called "developments of the invention, identified by the provisional specification," but which the opposing counsel contended were "departures from the provisional specification amounting to disconfirmity." These were the substitution for the to-and-fro movement of a rotary movement of the cells on the top for the mercury, and also the substitution as an alternative method of the rotation of the dish containing the mercury instead of the movement whether to-and-fro or rotatory of the cells, or the top of the mercury. The other addition made in the complete specification was the addition of a short-circuited current in the pure water cell, "starting from the mercury amalgam acting as an anode." This the defendants relied upon as another instance of disconformity, and also relied on it on the question of utility, alleging that the apparatus would not act without it, whereas the plaintiffs said that the "short-circuited current" was only to be used in case it was desired that the alkaline metal should be rapidly removed from the amalgam formed. The principal feature of the Kellner invention seemed to be (1) The substitution of non-circulating mercury for flowing mercury; (2) The subjection of the surface patches of the still mercury alternately to salt and water electrolyte and pure water respectively; (3) The maintenance, as far as possible, of the mercury in a still condition, free from agitation. The idea of the Rhodin patent seemed to have been to adopt the Kellner idea so far as it related to the movement of the salt electrolyte in a rigid vessel over the top of a stationary cathode, but to modify it so as to enable the use of a stronger electric current than that which could be used with the Kellner invention. Dealing with the defences set up in the action, his Lordship said that he thought the view taken by Mr. Justice Bigham, as to the meaning of the words in the Kellner's provisional specification "stationary mercury cathode," was right. It was clear that prior to the Kelvin patent inventors had always tried to get over the difficulty arising from necessity of quickly taking away the mercury when charged with the sodium deposited by electrolysis by causing the mercury thus charged to flow in the vessel containing it. The earlier inventions caused the mercury to flow when charged into a separate vessel or chamber when it was discharged of the sodium by contact of the amalgam with pure water, sometimes assisted by an electrical current passing through the second as well as the first chamber, and sometimes with the current passing only through the salt and water in the first chamber. Castner made the mercury flow in a single vessel underneath two rigid chambers, part and parcel of the same vessel. He read the word "stationary" as qualifying the word "mercury," and the words "stationary mercury" qualifying the word "cathode." The various defences set up by the defendants were these: (1) Denial of infringement; (2) Denial of the validity of the patent on the grounds (*a*) of want of novelty, by reason of the anticipations set forth in the particulars; (*b*) want of subject matter; (*c*) want of utility; (*d*) want of invention; (*e*) disconformity. With regard to the defences of disconformity and denial of infringement, which his Lordship considered together, it was said that the complete specification departed from the provisional, first because Figs. 7 and 8 introduced the rotary instead of the to-and-fro movement. It seemed to his Lordship that there was nothing in this, because if the invention of Kellner consisted of moving about a rigid body over stationary mercury in the sense in which he read those words, it seemed to him to be a legitimate development to say that in addition to movement by the to-and-fro method, the movement of the chamber over the stationary mercury might be attained by the rotary movement of the chamber over the stationary mercury, or by the rotation of the mercury dish over the chambers. In either case there was no flowing of the mercury relatively to the dish containing it. He thought that Mr. Justice Bigham was right, and that there was no disconformity, even in the case of the rotation of the bottom dish, because the mercury, even in this case, was stationary relatively to the dish containing it. As to the suggested disconformity, by reason of the claim in respect of the third electrode in the combining chamber, his Lordship thought there was nothing in it, because it was limited by the words at the beginning of claim 4, "In apparatus of the kind specified in preceding claims." His Lordship further thought that, assuming, as he did, that claim 3 was not bad for disconformity—assuming, that is, that there was no distinction between the rotary movement and the to and-fro movement, the infringement by the defendants of the Kellner patent was clearly established, even apart from important admissio of the leading counsel for the defendants, an admission which, for his own part, his Lordship thought he was right in making. Indeed, if it were not for the denial of Rhodin, he should have thought it tolerably clear that Rhodin's patent was framed by someone with Kellner and Castner's patents before him, seeking to extract the best portions of both. The total combination in the Rhodin apparatus seemed to his Lordship very different from the total combination in the Kellner apparatus. The result was arrived at by the application, in part at all events, of very different principles, but if Kellner's patent claimed, as his Lordship thought it, the use of stationary mercury relatively to the vessel containing it, and divided chambers, one of which was rotary, he thought that there was a clear infringement, and not the less so because Rhodin might have improved upon Kellner's apparatus by applying it to a novel and more effective apparatus. Dealing with the defence of anticipation, his Lordship said that the only anticipation seriously urged was the Castner process. It was said that the Kellner patent was anticipated by the Castner, because the movement of the chambers above the mercury was a mere mechanical equivalent for the flow of the mercury under the chambers. He (his Lordship) thought, not having regard to the object in view, Castner wanted to produce churning of the mercury; Kellner wished to avoid it. Castner's process did produce churning; Kellner's to a large extent avoided it and was intended so to do. Then it was said that Castner's double chamber was an anticipation of Kellner's double chamber. His Lordship thought that Castner's double chamber was fixed, and a part of a single structure. Kellner's was detached and movable, being, in fact, one of two rigid structures. Then, as to the defences of want of invention, want of utility and want of subject-matter, which, more or less hanged together, in his Lordship's opinion, all failed. He thought there was sufficient ingenuity to constitute an invention entitled to a patent, and that the invention was not only ingenious, but useful. It offered a method of producing caustic soda with a low electric current by dealing with surface patches of sufficiently still mercury, and that he considered was a distinctly new method. He came to the conclusion that the plaintiffs' apparatus was proved by the evidence to have sufficient utility, as affording, theoretically, a novel alternative mode of producing caustic soda by an electrolytic mercurial process. For those reasons he thought the judgment of Mr. Justice Bigham right.

The appeal was then allowed as previously announced.

Mr. TERRELL, Q.C., for the defendants, asked that the particulars of objections should be certified, for otherwise there would be a difficulty with the taxing master in allowing them.

Their Lordships decided that the matter should be mentioned to them again at a later date.

National Company for the Distribution of Electricity by Secondary Generators (Limited) v. John Dixon Gibbs and Henriette Onesime Ruelle.

This case came before Mr. Justice Cozens-Hardy, in the Chancery Division, on the 17th and 18th inst., and was an action brought by plaintiffs for specific performance of two agreements of May 25, 1883, and Oct. 31, 1883. The second defendant is the wife of Sylvain Jean Baptiste Ruelle and the administratrix of Lucien Gaulard.

It appeared that by the agreement of May 25, made between Lucien Gaulard and the defendant Gibbs, the vendors, and the plaintiff Company, it was agreed that the vendors should sell to the plaintiffs the exclusive privilege of using and vending certain inventions in connection with the manufacture and construction of secondary generators for the distribution of electricity, and other apparatus connected with electric lighting, for which the vendors had obtained letters patent in the United Kingdom, France, Belgium, Italy, Austria, Spain, New Zealand, India, Canada, Victoria, New South Wales, Queensland, South Australia, and Tasmania, and also all the said letters and patents and privileges, and the benefit of certain inventions and improvements for the sum of £220,000, to be paid as to £200,000 in 20,000 shares of £10 each of the plaintiff Company fully paid up, and £20,000 in cash. It was further agreed that the vendors should, at the expense of the plaintiff Company, establish a title to the inventions and letters patent and privileges, and should transfer the same to and cause the same to be legally vested in the plaintiff Company, and that the assignments to the plaintiff Company should contain a covenant by the vendors that all the letters patent were valid, and all such other covenants as might be required by the plaintiffs for giving effect to the sale. By the agreement of Oct. 31, 1883, made between the vendors and the plantiff Company, the former agreement was altered and varied so that the vendors should be paid by the plaintiff Company in lieu of the £20,000 in cash, a moiety of the moneys to be realised by the plaintiff Company from licences or concessions or agreements of any kind to use or work the inventions in question until such moiety should amount to £10,000, and the further sum of £10,000 residue of the sum of £20,000 cash, in 1,000 Preferred shares of £10 each, fully paid up. The plaintiffs alleged that they had allotted to the vendors the shares in question, and had paid to the defendant Gibbs £984 in cash, and to Gaulard £1,788 in cash, in pursuance of the agreements, but that the letters patent and privileges had not, in fact, been transferred to or assigned to the plaintiff Company, nor were the letters patent and privileges, in fact, valid. The plaintiffs also said that various persons had taken proceedings in France, the United States, Germany and Austria impeaching the validity of the letters patent and privileges granted in those countries, and as a result of those proceedings, the letters patent in respect of the United Kingdom had declared to be void, the Brevets d'Invention, in respect of France, Germany and Austria, had been declared to be invalid or restricted to such an extent that the remaining claims were of little or no value

Digitized by Google

The plaintiff Company had paid a large sum in respect of costs which they asked that the defendants might be ordered to repay, and also for so much of the purchase money paid to the defendants by them (the plaintiffs) as was properly attributable to the patents which had been declared to be wholly invalid, and of a due proportion of so much of the purchase money as was properly attributable to the patents which had been declared to be partially invalid.

Mr. Fletcher Moulton, Q.C., and Mr. Gore Brown appeared for the plaintiff Company; and Mr. Eve, Q.C., and Mr. Rowden for the defendants.

Mr. FLETCHER MOULTON said that Gibbs and Gaulard were people who were very well known in the early days of electric lighting. The plaintiffs estimated that by what had taken place the value of the patent was reduced by £50,000 in the United Kingdom. The learned counsel said that by the Gibbs and Gaulard invention it became possible to distribute electricity over very much larger areas than it was possible to do by the direct current, and which enormously diminished the expense of electric light installations. That was the fundamental patent for the distribution of electricity by secondary generators. If that patent was valid all persons setting up installations by secondary generators would have had to take licences from the plaintiffs. At the present moment one half of the installations over England were by this system, which reduced the cost of installations by something like 25 per cent. His Lordship would see that the value of the fundamental patent controlling the whole of that was enormous. If he (counsel) said that that patent was worth £1,000,000 he should not be exaggerating.

His LORDSHIP: What is the defence?

Mr. EVE said the defence was that there had been a release by the joint contractor, and that the action could not be maintained. The defendants also said that the thing was *res judicata*. His Lordship would find that as long ago as 1884 the parties chose to appeal to the French jurisdiction, and the case was subsequently dealt with by the French Courts, and he thought he should show his Lordship that all the points raised in the present action were decided in the French action. The last defence set up was that the plaintiffs had not carried out their part of the agreement. The defendants also counter-claimed of the amount found due to them in the French proceedings.

His LORDSHIP: Is there any point about the joint covenant?

Mr. EVE said there was, and he thought it would be convenient to deal with that point before the witnesses were called.

Mr. MOULTON said he did not think that defence was pleaded.

His LORDSHIP said that if the point arose on the documents there was no reason to plead it. He thought that the point went to the whole root of the action, and that he ought to hear counsel upon it at once.

A long legal argument then followed as to whether when letters patent were granted to two persons and one died the grant passed to the survivor. Mr. Fletcher Moulton submitted that the grant of letters patent to two persons was such a grant that if one died his executor took all his rights under the patent.

His LORDSHIP said he would consider his judgment on this point, and the further hearing would be adjourned till after this judgment was given.

Powell v. the Eastern Telegraph Co. (Limited).

In the High Court, before Mr. Justice Wills and a Special Jury, Mr. William Frederick Powell sought to recover damages from the Eastern Telegraph Co. for alleged wrongful dismissal and arrears of salary due.

It appeared that plaintiff entered into the defendant Cmpany's service in 1879 as an operator, and was stationed at Porthcurnow, Cornwall. In April, 1891, he entered into a written contract for five years' service, at home or abroad, and was entitled to three months' notice if defendants wished to terminate the engagement. A book of rules was subsequently issued by the Company, and a copy was sent to plaintiff. By one of these rules it was stipulated that after five years' uninterrupted service abroad an employé was entitled to four months' furlough at home on full pay. In 1893 plaintiff went on service to Gibraltar, and later was drafted to Alexandria, where he stayed till 1898. His health failed at Alexandria, and he suffered from dyspepsia and insomnia, and, having completed his five years' service, he applied for furlough, in accordance with the rule, and this was granted. He came to England in May, 1898, and his leave expired in September. His (plaintiff's) health did not improve during the interval, and he consulted Dr. Peyton, of Newport, where his father resided, and Dr. Peyton advised him that he was not in a state of health enabling him to go abroad. Plaintiff notified the defendant Company of this advice, and asked to be transferred temporarily to an English station, but the Company desired that their own doctor should examine him, and this was done, and in September he received a letter intimating that his leave had expired, and as the Company's doctor had reported him fit for duty, he was to proceed forthwith to Gibraltar. He replied by sending his own doctor's certificate to the effect that he was not in a state to leave England. The Company replied that they could only accept their own doctor's certificate, and ultimately plaintiff declined to enter into a fresh agreement for a further five years' service, and in October he was dismissed.

In cross-examination plaintiff said he did not tell his doctor that he had been offered a post at Gibraltar. He did not inform him to what country he was expected to go. His state of health was the real reason for his declining to go abroad. When he was stationed at Gibraltar previously his health had been good.

Dr. ARTHUR CÆSAR, acting medical officer to the Eastern Telegraph Co., said he saw the plaintiff twice in September, when he complained of dyspepsia and insomnia. Witness was of opinion, however, that he was in good health, and quite fit for duty. He had, however, made no note of the case, and had not sent a report to the Company.

Further evidence showed that the original rules, as supplied to plaintiff in 1891, had been amended, and it was now provided that privilege leave was only granted on condition that the employé returned for a further period of service, and the Company reserved the right to recover the amount of salary paid to an employé while on leave should he fail to return to the service. It had been found necessary to make this new rule, as clerks had frequently taken their four months' furlough on full pay and then declined to return for service abroad. A copy of the rule was posted up in the office at Porthcurnow while plaintiff was there, and it was suggested that he knew the rule. As he declined to contract for a further period of service, the defendants contended they were justified in dismissing him.

The jury found that the order given to plaintiff to go to Gibraltar was an unreasonable one, and that he did not know of the new rule which required employés on coming home on furlough to enter into fresh agreement for service with the Company.

On these findings judgment was given for plaintiff for £112, the amount claimed, and costs.

Ashwell and Nesbit (Limited) v. Stanton.

In the Divisional Court on Friday, before Mr. Justice Wills and Mr. Justice Ridley, Mr. Manisty moved, on behalf of the defendant, Mrs. Stanton, to set aside the findings and judgment of Mr. Pollock, the official referee, in an action tried before him at Leeds, by which he gave judgment for plaintiffs on their claim for £500, and on the defendant's counter-claim. The action was brought by plaintiffs, who are electric light engineers and contractors, at Leicester and Nottingham, to recover £500 in respect of work done under two contracts. The defence was that the work had not been completed in accordance with the terms of the contract, and that it was defective; further, there was a counter-claim that the work was done on the terms of an express assurance given by the plaintiffs that the work should be completed on Nov. 4, 1897, so as to enable the defendant to open certain business premises in Leeds on that date, and that, relying on the faith of that assurance, she incurred large expense in advertising the opening of the premises and engaging assistants; and the work was not completed by that date. The consideration for the promise that the work should be completed on Nov. 4 was that she incurred great expense on the faith of the promise, and if a person incurred expense on the faith of an assurance that gave him cause of action. The referee held that there had been consideration for the promise, but he said the terms of the promise had been complied with, and there had been no breach. His (counsel's) point was that there was a clear breach, having regard to the proper construction of the promise. As a fact, the premises were not ready till December, and the electric lighting was not in order until December 10th. He read the findings of the official referee, from which it appeared that it was not the fittings provided by the plaintiffs which were not completed at the date promised, but a gas engine that had not arrived, and the referee found that it was not the fault of the plaintiffs that the work was not completed. Defendant had, however, contracted with plaintiffs to supply the whole installation complete, and, therefore, he contended that the official referee was wrong in his finding. There was no written contract, but there was a verbal agreement that the whole of the works should be completed and in running order by November 4, and that guarantee was not carried out.

After hearing evidence in opposition to the motion their Lordships held that the referee was wrong and that the plaintiffs gave an unqualified assurance, but final judgment was reserved to enable another point to be considered.

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning. New Catalogues, Price Lists, and similar matter should be sent early in the week.]

NEW BOOKS AND EDITIONS.

The following New Books and Editions can be obtained of the Booksellers or direct from the Publishing Offices, 1, 2 and 3, Salisbury-court, Fleet-street, London:—

NOW READY.

"LABORATORY NOTES AND FORMS."—With the above title we have ready the New Edition of a set of 40 Elementary and Advanced Exercises for use in Electrical Engineering classes. These have been prepared by Dr. J. A. Fleming, and will be found of great service to Teachers, Demonstrators and Students. The object of this series is the saving of the time of the Teacher and his Assistants, and to serve as a record of the work done by the Student. Each Form is supplied either singly at 4d., or 3s. 6d. per dozen net; in sets of any three, 1s. net; or the set of Twenty (Elementary or Advanced) Exercises can be obtained, price 5s. 6d. net. The complete set of Twenty Elementary and Twenty Advanced Exercises are price 10s. 6d. net; or in handy portfolio, price 12s. net; or bound in strong cloth case, price 12s. 6d. net. Strong portfolios can be had, price 1s. each.

NOW READY.—The cheaper edition of Dr. J. A. Fleming's "Electrical Laboratory Notes and Forms." These cheaper Forms have been prepared for the use of students and teachers at the Polytechnic and other science classes throughout the country. The demand for the original set of these Notes and Forms has led to a request for a cheaper set for use at the day and evening classes at many of the technical institutes. These new Forms, which differ only from the higher-priced set in being printed on smaller and cheaper paper and with less space for tabulated records, are issued at half the price of the original set.

"ELECTRICAL TESTING FOR TELEGRAPH ENGINEERS."—By J. Elton Young, M.I.E.E. The scope of the book aims at furnishing a fuller treatment of the subject, from the standpoint of the Telegraph Engineer, than it has hitherto received, whilst it endeavours to facilitate a thorough comprehension of the theory of testing as applied to electrical lines in general. Demy 8vo, fully illustrated. 10s. 6d., post free; abroad 11s.

Digitized by Google

"THE STUDENTS' GUIDE TO SUBMARINE CABLE TESTING."—A new work by Messrs. H. K. C. Fisher and J. C. H. Darby, with the above title, is now ready, price 6s. net; abroad, 6s. 3d. This work is intended to serve as a guide to operators already in the telegraph service, and to those who desire to enter that service. The great cable companies now insist that their operators and probationers shall pass certain examinations in electrical subjects. The book is very fully illustrated. *Second Edition now ready.*

"SUBMARINE CABLE-LAYING AND REPAIRING."—By H. D. Wilkinson, M.I.E.E., &c., fully illustrated; price 12s. 6d.

"PRACTICAL NOTES FOR ELECTRICAL STUDENTS."—By Messrs. A. E. Kennelly and H. D. Wilkinson. Price 6s. 6d., post free.

"ELECTRO-CHEMISTRY."—By Dr. G. Gore. Third Edition. Price 2s., post free.

"ELECTRIC MOTIVE POWER," by Albion T. Snell, contains the latest information respecting the application of electric energy to mining and general power transmission purposes, in which the author has had much experience. Price 10s. 6d., post free; abroad, 11s. *New edition ready May 1, 1899.*

"WIRELESS TELEGRAPHY: SIGNALLING ACROSS SPACE WITHOUT WIRES BY ELECTRIC WAVES."—By Dr. O. J. Lodge, with many original illustrations. *Enlarged Edition*, 2s. 6d. net, 2s. 9d. post free.

"ELECTROMAGNETIC THEORY."—By Oliver Heaviside *Vol. I.*, 12s. 6d. *Vol. II. ready May 1, 1899.*

"THE INCANDESCENT LAMP AND ITS MANUFACTURE."—This book, written by Mr. Gilbert S. Ram, is now ready. Price 7s. 6d.; abroad, 8s.

"THE STEAM ENGINE INDICATOR AND INDICATOR DIAGRAMS."—Edited and enlarged by W. Worby Beaumont. Price 3s. 6d., post free.

"THE ART OF ELECTROLYTIC SEPARATION OF METALS."—A second issue of Dr. Gore's book is now ready, price 10s. 6d., post free.

"THE MANUFACTURE OF ELECTRIC LIGHT CARBONS."—A Practical Guide to the establishment of a Carbon Manufactory. Fully illustrated price 1s. 6d.; post free, 1s. 9d.

"THE BIBLIOGRAPHY OF X-RAY LITERATURE AND RESEARCH, 1896-97." A valuable, up-to-date compilation. Being an attempt to classify the data relating to X-Ray work. This work contains a quantity of genera as well as special information bearing upon the whole subject of electrica discharge research. Price 5s., post free; abroad, 5s. 3d.

"LOCALISATION OF FAULTS IN ELECTRIC LIGHT MAINS."—By F. C. Raphael. Price 5s., post free; abroad, 5s. 6d. Prospectus on application.

"ELECTRICAL ENGINEERING FORMULÆ," a pocket-book, by Messrs. W. Geipel and H. M. Kilgour; price 7s. 6d.; by post, 7s. 9d.; abroad, 8s. A fine large paper edition with wide margins for notes can also be supplied. Price 12s. 6d.; post free, 13s.; abroad, 13s. 6d. *New Edition in the press.*

"THE ALTERNATE CURRENT TRANSFORMER," Vol. I.—By Prof. J. A. Fleming, M.A., D.Sc., F.R.S. *New Edition.* Price 12s. 6d., post free. Vol. II., price 12s. 6d. post free, is also ready.

"ELECTRIC LAMPS AND ELECTRIC LIGHTING," by Prof. J. A. Fleming, M.A., D.Sc., F.R.S., is handsomely bound, and full of original illustrations, designs, initials, &c. Price 7s. 6d., post free.

"THE ELECTRICIAN" PRIMERS.—In Two Volumes. Vol. I., Theory. Vol. II., Practice. Price, stout paper cover, 2s. 2d. each, post free; cloth, 2s. 9d. Single Primers, 8d. each, post free.

"THE POTENTIOMETER AND ITS ADJUNCTS": A Universal System of Electrical Measurement.—By W. C. Fisher. Fully illustrated. Price 6s. post free; abroad, 6s. 6d. Digest post free.

"DRUM ARMATURES AND COMMUTATORS," by Mr. F. Marten Weymouth, also ready. Price 7s. 6d.; abroad, 8s. Prospectus on application.

"MOTIVE POWER AND GEARING FOR ELECTRICAL MACHINERY."—By E. Tremlett Carter, C.E., M.I.E.E. Price 12s. 6d., post free; abroad 13s. 6d. Prospectus post free.

"ARMATURE WINDINGS OF ELECTRIC MACHINES."—By H. F. Parshall and H. M. Hobart. This work has been compiled from notes made by Mr. Parshall in his capacity as Chief Designing Engineer of the Edison and General Electric Companies of America, and is intended to serve as a working treatise on dynamo design. Large 4to, 370 pages, 140 full-page illustrations and 65 full-page tables, 30s., post free.

"The Electrician" Electrical Trades' Directory and Handbook for 1899.—The "Big Blue Book" for 1899 is NOW READY. The Directory Division has been corrected up to Feb. 8, 1899, and all the latest new names, changes of address, &c., will be found included. The Handbook Division has been much extended, many valuable tables having been added. The volume contains, also, the large Sheet Tables of Electricity Supply Stations and Electric Railways and Tramways, finally corrected to Feb. 9, 1899. The price of the Directory and Handbook remains the same—10s., post free 10s, 9d.; abroad, post free, 12s. (United States 13s. 6d.).

TENDERS INVITED.

As advertised elsewhere, the *Epsom* District Council invite tenders for the supply and erection of: (*a*) Lancashire boilers and fittings, economiser, feed pumps, &c.; (*b*) pipework, &c., in engine and boiler house; (*c*) steam dynamos and motor boosters; (*d*) storage batteries; (*e*) main switchboard and connections; (*f*) overhead travelling crane; (*g*) underground mains and conduits; (*h*) arc lamps and posts; (*i*) street glow lamps and accessories; and (*k*) station lighting. Specifications, &c., may be obtained from the consulting engineer (Mr. W. C. C. Hawtayne), 9, Queen-street-place, London, E.C., on and after the 10th inst. Tenders to the clerk (Mr. E. G. Wilson), High-street, Epsom, by noon of May 8.

The *Belfast* Electric committee also invite tenders for laying conduits and building junction boxes and for laying cables. An advertisement contains further particulars. Specifications, &c., may be obtained from the city electrical engineer (Mr. Victor A. H. McCowen), and tenders must be lodged at the office of the town clerk (Sir Samuel Black) by noon of Thursday, 27th inst.

The Vestry of *St. Pancras* (London) invite tenders for supplying and fixing additional plant, comprising dynamos, engines, &c., at the Regent's Park electricity works. Further particulars are given in an advertisement, and tenders must be sent to the vestry clerk (Mr. C. H. F. Barrett), Vestry Hall, Pancras-road, N.W., by noon of Tuesday, May 16.

The *Darlington* Corporation invite tenders for the supply and erection of:—(1) Lancashire boilers, with mechanical stokers; (2) engines, dynamos, pumps, pipes, &c., Green's economiser and tools; (3) storage battery; (4) switchboard and boosters; (5) arc lamps; (6) feeders, mains and arc light leads, including roadwork. Further particulars are given in an advertisement. Plans and specifications can be obtained at the office of the borough surveyor. Plans can also be seen at, but not obtained from, the office of the consulting engineer (Prof. Alex. B. W. Kennedy), 17, Victoria-street, London, S.W., and tenders must be lodged with the town clerk (Mr. Hy. G. Steavenson), Town Hall, Darlington, by May 8.

The Vestry of the parish of *St. Mary, Battersea* (London), require tenders for the supply and erection of (1) feeders, distributing mains, and arc light leads (including laying and jointing); (2) watertube boilers; (3) steam dynamos and engines. Tenders to to clerk (Mr. W. Marcus Wilkins), Municipal-buildings, Lavender-hill, London, S.W., by noon, June 7. An advertisement gives further particulars.

The *Hampstead* (London) Vestry require two 500-kilowatt steam alternators, five Ferranti or similar type switchboard panels, boilers, feed-water heaters, feed pumps, a 40-kilowatt exciter, water softening plant, air pump and condenser, economiser, overhead travelling crane, &c. Tenders to the clerk by noon of May 18.

The Town Council of *Reigate*, Surrey, require tenders for (1) two water-tube boilers, economiser, brickwork, and flues, (2) steam exhaust and other pipes, steam pumps, &c., (3) two 100 kilowatt and one 20 kilowatt steam alternator, 8-ton overhead travelling crane, and sub-station equipment, (4) switchboard and instruments, (5) mains, lamp-posts, lamps and fittings. Tenders to town clerk, 84, Station-road, Redhill, by noon May 1.

The *Salford* Electric Light committee invite tenders for the supply of 3,220 yards of 0·2 high tension concentric lead-covered cable, compound insulation. Tenders to the office of the town clerk by 9 a.m. 28th inst.

The *Darlington* Corporation require tenders for the erection of electricity station buildings. Tenders to town clerk by May 8.

The *Southampton* Corporation invite tenders for the reconstruction of about 1¾ miles of tramway. Tenders to acting town clerk by May 2.

The *Wallasey* District Council invite tenders for the supply of electric stores, including meters, insulated concentric cables, main switches and cut-outs. Tenders to clerk, Egremont, Cheshire, by 9 a.m. of 24th inst.

The *Ealing* Council invite tenders for two Lancashire boilers with superheaters and accessories. Tenders to clerk by May 1.

The *Morley* (Yorks) Corporation invite tenders for wiring the public baths. Tenders to town clerk by 4 p.m. 26th inst.

The Visitors' committee of the *Isle of Wight* County Asylum, Newport, invite tenders for a combined engine and dynamo giving an output of 400 amperes at 110 volts. Tenders by 29th inst.

The *Edinburgh* Corporation invite tenders for twelve months' supply of:—(1) steam coal, (2) arc lamp carbons, (3) cast iron pipes, pavement box frames, &c. Tenders to town clerk by 24th inst.

The *Poplar* (London) District Board of Works invite tenders for engine and pump room equipment and all electrical plant except battery; boiler house equipment; battery and battery stands; and public street lighting. Tenders by 10 a.m. April 25.

The *Hull* School Board invite estimates for the installation of the electric light at the central higher-grade school and school of science. Tenders to clerk by 25th inst.

The *West Ham* Council invite tenders for two 1,500 I.H.P. engines, two 800 kilowatt alternators and exciters, Tenders to town clerk by 4 p.m. April 25.

The *St. Marylebone* (London) Guardians invite tenders for the wiring of the new front blocks of their workhouse in Northumberland-street, W. Tenders to clerk by May 8.

The *French* Post and Telegraph authorities invite tenders, until 4th May, for the supply of 666 metres of paper insulated electric cable. Tenders to Le Sous-Secretariat d'Etat des Postes et des Telegraphes, Rue de Grenelle 103, Paris.

Tenders are being invited, until May 18, by the municipal authorities of *Ferrol*, for the concession for the electric lighting o

Digitized by Google

the town for 15 years. Particulars from and tenders to el Secretario del Ayuntamiento de Ferrol, Spain.

The Municipal Authorities of *Tarifa* invite tenders until May 16 for the concession for the electric lighting of the town for 20 years. Tenders to el Secretario del Ayuntamiento de Tarifa, Spain.

TENDERS RECEIVED AND ACCEPTED.

Correction.—By a clerical error in our note last week of the acceptance of tenders by the Gloucester City Council it was stated that the British Insulated Wire Co. had been allotted the contract for public lamps. We learn that the tenders for this section of the work are still under consideration.

The following tenders have been received by the Barking District Council for the supply and erection of one 80 kilowatt steam dynamo (vertical high speed engine and two-pole dynamo) with pipe work and accessories :—

Sunderland Forge Co. (*accepted*)	£945	Musgrave and Co. (Thomson-Houston dynamo)	£1,374
Crompton and Co. (Willans engine)	1,790	E. Scott and Mountain	1,255
Willans and Robinson (Crompton dynamo)	1,657	D. Bruce Peebles and Co. (Willans engine)	1,247
Geo. Wailes and Co.	1,612	D. Bruce Peebles and Co. (Alley & McLellan engine)	975
Electric Construction Co.	1,546	Brush Co.	1,226
McClure and Whitfield	1,490	Mavor and Coulson	1,002
Brush Co. (100 kilowatt set)	1,424	Ditto (larger engine)	1,168
Musgrave and Co. (Mather and Platt dynamo)	1,396	General Electric Co.	1,053
		Foote and Milne	1,002
		Ditto (larger engine)	1,030

The Glasgow Corporation have accepted the offer of Messrs. M'Dowall, Steven and Co., for the supply of the lamp pillars to be erected on Glasgow Bridge to carry the trolley wires and arc lamps for the electric lighting of the bridge.

The Southampton Corporation have accepted the tender of the Leeds Steel Works Co., for 1,200 tons of rails and fishplates at £7. 5s. per ton.

The Islington (London) Vestry have accepted the tender of Mr. Oscar Scholzig for the supply of electric light carbons during the ensuing year.

The Shoreditch (London) Vestry have accepted the tender of Messrs. S. Minns and Co. for the supply of boiler fluid for the Lighting committee and that of Messrs. Middleton Bros. for engineer's stores.

APPOINTMENTS VACANT AND FILLED.

The Belfast Electric committee require an assistant electrical engineer. Further particulars are given in an advertisement, and applications must be lodged with the city electrical engineer (Mr. Victor A. H. McCowen), Central Station, East Bridge-street, Belfast, by Tuesday, 25th inst.

The Gas committee of the Keighley Corporation require an electrical engineer to prepare specifications, &c., of an electric lighting scheme. Applications (addressed chairman of committee) to town clerk by May 1.

The Sheffield Corporation require a mains superintendent. Applications to manager and engineer by 27th inst.

The Central London Railway Co. require a traffic superintendent and an accountant. Applications to secretary, 16, Great George-street, S.W., by 29th inst.

Mr. Charles H. Furness has been elected borough electrical engineer by the Devonport Council, the apointment to date from June 1, Mr. Furness in the meantime to gratuitously render such assistance as will not interfere with the discharge of his existing obligations to Messrs. Veale and Co. Out of the applications received the following were reserved for special consideration :—Messrs. A. Arthur Mahood (Hanley), James T. Baron (London), Charles Furness (Plymouth), W. Howard Tasker (London), E. G. Okell (Plymouth), Wm. T. Proctor (Nuneaton), W. R. Wright (Burnley), and J. B. Mitchell (Southend).

Mr. W. C. P. Tapper, who has been for nearly five years one of the chief assistants of Mr. Arthur Wright, at the Brighton Electricity Works, and who has for some time past acted as chief engineer for Mr. Wright in his London work, has been appointed resident electrical engineer to the Whitechapel District Board of Works, to carry out the electric lighting of that district under Mr. Wright's supervision.

Mr. H. Haskayne, assistant superintending engineer for the South Wales district of the Post Office, has been appointed superintending engineer for the North-Western district, in succession to Mr. J. Doherty, retired.

BUSINESS NOTICES.

Messrs. A. W. Jackson and F. J. Coleby (trading as Jackson and Coleby), electrical engineers, 7, Thayer-street, Manchester-square, London, W., have dissolved partnership. Debts by Mr. Coleby, who continues in his own name.

Messrs. F. Hodgson and A. H. Hodgson (trading as Frederick Hodgson and Co.), electrical engineers, 56, Gresham-street, London, E.C, have dissolved partnership.

Messrs. Sax, Slatter and Co. (Limited) ask that all future communications be addressed to Foresters' Hall, Clerkenwell, London, E.C.

The London office of Messrs. W. H. Allen, Son and Co. is now 27, Old Queen-street, Westminster, S.W.

BANKRUPTCIES, LIQUIDATIONS, &c.

In the London Bankruptcy Court, before Mr. Registrar Brougham, Edward Baldwin Pym, electrical engineer, formerly of Scarborough, and now of Burnham, was publicly examined on Friday last, on accounts showing liabilities £3,744, assets nil. Debtor said he had been entitled, under the will of his uncle, to a life interest in £10,000, but that had been terminated by the bankruptcy proceedings. He only owed about £130 in respect of his electrical business. His business at Scarborough was not successful, and he had been concerned in various bill transactions. Examination concluded.

A meeting of the Coventry Electric Tramways (Limited) (in voluntary liquidation) will be held at 17, Hertford-street, Coventry, on May 17, to receive an account of the winding up.

J. E. Stott (trading as James E. Stott and Co.), electrician, 10, Wood-street, Byram-arcade, and 9, Westfield-road, Huddersfield, has been adjudicated bankrupt. First meeting of creditors 24th inst., at 19, John William-street, Huddersfield ; public examination 28th inst., at County Court, Huddersfield.

James Stephen Blackwell (partner in Charles and Blackwell, trading as the Central Electrical and Engineering Co.), 74 and 111, Church Gate, Leicester, and 22, Kennington-road, London, has been adjudicated bankrupt.

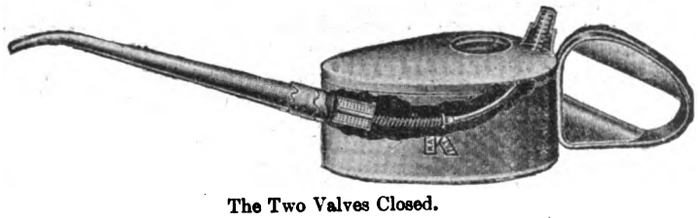
Claims against the London Motor Car Works Co. (Limited) must be in by May 5 to Mr. S. Wheeler, 33, Carey-street, London, W.C.

Sale by Auction.—This day (Friday) Messrs. Wreford and Brown will sell at their auction rooms, 44A, Wilton-road, London, S.W., at 6:30 p.m. precisely, a quantity of shop-soiled and new electric light fittings. See advertisement.

Plant for Sale.—Messrs. Laurence, Scott and Co., Limited, Gothic Works, Norwich, have lathes and a drilling machine for disposal. See advertisement.

Improved Oil Cans.—More than 30 years ago Mr. Joseph Kaye, senior partner in the firm of Joseph Kaye and Sons (Limited), of Leeds and London, first obtained letters patent for

The Two Valves Open.



The Two Valves Closed.

improvements in oil cans. Since this time 20 patents have been granted to him for such improvements. The illustrations we give below show the perfection to which Mr. Kaye's oil can has arrived. Messrs. Kaye were the first makers to produce a seamless oil can fitted with a patent slide feed-hole, and they still claim four valid patents in this connection. One of these is the valve thumb button. This improvement consists in the thumb button being loose (not soldered as hitherto) at the top of the valve spindle. When the pressure of the thumb is released, the spiral spring, within the bell-shaped sleeve A, pushes the button back to its seating—the latter forming a valve and sealing the top of the can. This prevents waste of oil and the possibility of the thumb button being broken off. These useful cans are in use all over the world in thousands, and need no further recommendation. These latest improvements will serve to increase their popularity.

The "Journal."—Part 139 of the *Journal* of the Institution of Electrical Engineers is now ready. Its contents are set out in an advertisement elsewhere.

Digitized by Google

"Strand" Watches.—An interesting announcement is made in an advertisement on another page, by Messrs. S. Smith and Son (Limited), the well-known watch and chronometer makers, of 9, Strand, London, with regard to the safeguard offered by the firm to watch buyers by a perfected system of identification, by which the buyer can assure himself that he has the actual watch selected. This enterprising firm also announce that they have adopted a system of payment by monthly instalments for the well-known "Strand" watch, a large number of which are in use by electricians in all parts of the world. A not unimportant point to be observed is that Messrs. S. Smith and Son are actual manufacturers of the goods offered.

Fuel Economisers.—We learn that the "Green" fuel economiser has been selected by the East End Electric Railway Co., New York, in keen competition with other makes of this class of apparatus for use at the extensive power station about to be built by the company. The contract, which we believe to be the largest on record, amounts to about 10,000 tubes. These economisers are manufactured by Messrs. E. Green and Co., of Manchester.

The Duddell Oscillograph.—The Cambridge Scientific Instrument Co., of Carlisle-road, Cambridge, inform us that they are the sole makers of the oscillograph shown by Messrs. Duddell and Marchant at the Institution of Electrical Engineers last week.

Patent Amendment.—As advertised elsewhere Charles Howard, 67, Lerchenfelderstrasse, and Dr. Robert Mayer, 18, Taborstrasse, Vienna, have applied for leave to amend the specification of letters patent No. 23,623 (1897) for "An improved process of manufacturing electric incandescent lamps." Objections must be lodged by May 12.

Exports of Electrical Apparatus and Material.—The following list gives official particulars of the exports of British manufactured electrical apparatus and material (including telegraph and telephone wire and material, but not including electrical instruments or machines, which are not separately specified) from April 12 to April 18, with the ports of destination:—

Aden, £150 (including £50 telegraph material). *Argentina*—Buenos Ayres, £1,079 (including £84 telegraph material). *Australasia*—Launceston, £15; Melbourne, £4,516 (including £4,421 telegraph cable); Sydney, £800. *Belgium*—Antwerp, £27. *Brazil*—Rio Grande, £30. *Ceylon*—Colombo, £54. *China*—Shanghai, £152; Tientsin, £25. *Columbia (Republic of)*—Santos, £244 (including £104 telegraph material); *Denmark*—Copenhagen, £110. *Egypt*—Alexandria, £129. *Germany*—Hamburg, £115. *Holland*—Amsterdam, £54; Rotterdam, £35 (telegraph material. *Hong-Kong*, £45. *India*—Calcutta £434; Madras, £197. *Italy*—Genoa, £70; Spezia, £245. *Japan*—Yokohama, £178. *Madeira*—£29. *Mauritius*—£25. *Russia*—St. Petersburg, £10 (telegraph material). *Siam*—Bangkok, £125. *South Africa*—Cape Town, £1,379; Durban, £343 (including £220 telegraph material); East London, £33; Port Elizabeth, £329. *Straits Settlements*—Singapore, £10. Total £10,987, against £30,363 for 12 days last year (April 8 to 19).

MUNICIPAL, FOREIGN AND GENERAL NOTES.

Ambleside.—The question as to whether the Council should establish municipal electricity works or take current from the Windermere and District Electric Light and Power Co. was debated at the last meeting. Mr. C. Hopkinson, the Council's consulting engineer, said he calculated that a municipal scheme would cost about £3,800 and he was in favour of establishing an independent installation. Further consideration has been adjourned for a fortnight.

Bangor.—The Lighting committee on Wednesday reported that they had obtained signed agreements and verbal promises to take electric current from the Corporation to the amounts of 30,360 units and 16,800 respectively (7,160 units more than the amount stipulated for in the resolution passed at the last meeting), and the Council was, therefore, recommended to accept the agreements and promises in lieu of the guarantee by councillors, and to proceed forthwith to erect electricity supply works; also that the report of the engineer (Mr. F. H. Medhurst) be adopted, and that tenders for the work (amounting to £1,3052. 6s. 7d.) be accepted. The committee's recommendations were adopted in their entirety.

Barmouth.—The Board of Trade have intimated to the Council that they have refused Mr. D. Davies' application for a provisional order, but in the event of the Council applying for an order they would not agree to the insertion of any clause giving power to transfer the order to a company.

Beccles.—In a recent report to the Council, Mr. F. H. Medhurst states that there is every prospect of an electricity supply scheme being successful in this town. He estimates the cost of a scheme to provide for public and private lighting at about £12,500.

Belfast.—A sub-committee has been appointed to consider certain proposals made to the Council in connection with the purchase of the Belfast Street Tramways Co. The town clerk (Sir Samuel Black) has prepared a report, and estimates the cost of conversion of the lines into electric lines at £350,000.

Bermondsey (London).—The appeal of the London Electric Supply Corporation against the refusal of the Vestry to sanction the laying of mains on both sides of the streets has been decided by the Board of Trade. With the exception of Bermondsey New-road the mains are to be placed on one side of the street only, where trunk mains already exist, the company are, as far as possible, to lay the new mains under or over the trunk mains, and should the company at any future time require to lay a main on the other side of any street notice must be given to the Vestry.

Bradford.—The borough electrical engineer (Mr. A. H. Gibbings) has been instructed to report upon the revision of the charges to large consumers of electric current for motive power. A sub-committee recommends the acceptance of a tender for new batteries at £3,000.

Cardiff.—Messrs. S. F. Walker and Co. have intimated to the Corporation that they are willing to take electric current for motive power, provided a supply is given at 2d. per unit. A guaranteed minimum consumption of 4,500 units per annum is made. The present charge for current for motive power is 2½d. a unit, and the borough electrical engineer (Mr. N. Appelbee) has been asked to report upon the advisability of reducing this scale.

Cheltenham.—The Corn Exchange is now lighted electrically. Incandescent lamps of an aggregate of 1,200 c.p. are employed and current is taken from the town mains.

Chile.—An Act has recently been passed by the Chilian Congress, empowering the President of the Republic to expend 50,000 dollars on the survey of a line of telegraphs from Punta Arenas to Puerto Montt.

Cuba.—The duty imposed by the United States upon dynamo electric machines, inductors and detached parts is 20 per cent. *adval.*

Devonport.—The Council have adopted a motion in favour of lighting all the main roads in the outer wards electrically forthwith.

Dock Lighting.—The Mersey Dock and Harbour Board have decided to erect arc lamps at the new Canada Graving Dock, at an estimated cost of £700.

Dublin.—Application was made to the Dublin Grand Jury on Monday, on behalf of Mr. J. M'Auley and Mr. W. Mc'Dermott, for approval of a scheme for the construction of an electric tramway between the terminus of the Dublin and Lucan Tramway and Leixlip. The Grand Jury approved the scheme subject to certain conditions.

Dunblane.—Edmundson's Electricity Corporation have submitted proposals for establishing electricity works for Dunblane and Bridge of Allan, and a joint committee of the two Boards of Commissioners are considering the scheme. Gas in Dunblane is 5s. 5d. per 1,000.

Electric Traction in London.—It will be remembered that the London County Council is seeking powers to dispense with standing orders to introduce a Bill to enable the Council to use the trolley, conduit, or surface contact system on the Council's tramways, and to utilise the roads without the consent of the local authorities. Beyond the issue of the usual notices in the *London Gazette*, the Council has not thought fit to acquaint the local authorities of its intention to supersede them as the road authority in this respect. These facts have been brought before the Lambeth Vestry in connection with the Council's application to the Board of Trade for a license to adopt mechanical traction on the Westminster Bridge–Tooting route, and the Vestry have decided to oppose the petition, but the Vestry will consider the application if the form of traction to be used is specified.

Fire.—When the cause of a fire is not easily discoverable it has become the custom to put the blame on "defective electric light wires," and the recent serious fire at Hyde Park Court was no exception to the rule. As will be seen from the following letter from Mr. A. H. Howard, A.M.I.C.E, M.I.E.E., consulting engineer to Hyde Park Court, there was apparently no justification whatever for the assertion:—

"A statement has been widely circulated by the press that the fire at Knightsbridge was caused by a defect in the electric light wires. There is no foundation for this assertion beyond the fact that the fire was first seen in a place where there are several electric light wires. An exhaustive inquiry was held yesterday [Wednesday] by representatives of the insurance companies interested and of the Salvage Corps together with the Directors and officers of the Hyde Park Court Co. Eighteen witnesses were examined, and the unanimous opinion was that the fire first broke out in the turret, which is above everything else in the building, and that it had no connection with the electric light wires. A proof of this lies in the fact that the chief part of the damage was done in the turret and the floor into which the turret opens immediately below, while the fireproof doors and walls effectually prevented the fire from penetrating beyond the part where it originated, viz., the turret and top floor facing Knightsbridge. Electricity has most unjustly become a scapegoat to carry the blame for fires whose origin is obscure, and I trust you will insert this letter to show that in this case it is in no way to blame."

"Free" Wiring.—The Tunbridge Wells Corporation and the Salisbury and the Northampton Electric Lighting Companies have entered into arrangements with the National Electric Free Wiring Co.

Digitized by Google

Germany and Japan.—In the recently concluded tariff convention between Germany and Japan the duty on telegraph or galvanised wire of iron or mild steel is fixed at 0·256 yen per 100 catties. All other telegraph wire pays an *ad val.* duty of 5 per cent.

Glasgow.—An inquiry was held here on Wednesday by Sheriff Berry, at the instance of the Lord Advocate on behalf of the Postmaster-General, in which his lordship is asked to intervene between the Post Office authorities and the Corporation as to laying telephone lines under the city streets. Mr. K. Craigie, for the Corporation, said the Postmaster-General urged that he was entitled to the authority to lay the wires whether the Corporation acquiesced or not, and he was not to agree to the condition that the Corporation would only grant that consent provided it was not to be made applicable to the purposes of any private company. The Corporation's position was that it was not judicious to give a company a right to use their streets, because such right would deprive them of the control of the streets. This application was a fraud on the Corporation. Refused permission by the municipality, the telephone company incited the Postmaster-General to apply in his own name. Mr. Fleming, advocate for the Postmaster-General, said that it was the intention of the Government to give permission to lay a junction wire between Douglas-street and the Central Exchange of the company. Mr. Thomas Shaw, Q.C., M.P., contended that there was the same veto against operations by the Postmaster-General as was provided by the Act of 1892 against private companies. Mr. Henry Johnstone, Q.C., said what his lordship had to determine was whether a municipality was entitled to dictate to the Postmaster-General what use he would make of pipes laid down under the streets under his statutory powers. The telephone was part of the telegraph system, and the Postmaster-General had power to grant licences and apply for wayleaves from municipalities. Sheriff Berry announced that he would shortly give his judgment.

Greenock.—Mr. John Young has prepared his report on the municipalisation and electrical equipment of the tramways with great expedition. There is no doubt in Mr. Young's mind that the Police Board could successfully work the tramways within its own boundary, independently of the sections within Port-Glasgow and Gourock. Exclusive of rolling stock, he estimates that to renew the tramways throughout, double the existing single lines, and electrically equip them would cost about £96,400. With the prospect of serving three burghs, representing a resident population of about 85,000, in addition to the large influx of summer visitors, Mr. Young would recommend a 7½ minute service in the thickly-populated part of the route in Port-Glasgow and Greenock, and a 15 minute service on the Gourock end, with augmentations at busy times. The total capital expenditure is put at £159,680, the average revenue for the first three years (at 11d. per mile) at £25,086. 10s., working expenses at £13,689, and after deducting interest, sinking fund and depreciation, there would be a credit balance of £229. 18s. For the following three years the credit balance would be £2,238. 8s., and afterwards £4,633. 8s., on a regularly increasing traffic. The proposal of the Board to grant a lease, with option of purchase, at 14 or 21 years, would be much more costly, as the valuation would be based on the profit-earning capacity of the undertaking, and, accordingly, Mr. Young advises the Board to municipalise the whole system within and without the burgh. Proposals of the Port Glasgow Tramways Co. and Mr. W. M. Murphy are under the consideration of the Board.

Hornsey.—The question of putting the Council's electric light provisional order into force has been referred to a special committee. The chairman said he should oppose the scheme at every stage. Several offers to take over the order have been received, but have been declined.

Hull.—A further loan of £15,500 for electricity supply purposes has been sanctioned by the Local Government Board.

Ibero-American Benevolent Society.—The ninth annual banquet in aid of the funds of this deserving charity will take place at the Hotel Cecil, London, on Friday, May 5, at 7 for 7:30 p.m. The executive committee include the chief Spanish and Spanish-American residents in London, and the stewards include Mr. Ch. Gerhardi, manager of the Direct Spanish Telegraph Co., Winchester House, Old Broad-street, London, E.C., to whom donations may be remitted, and from whom tickets for the dinner can be obtained.

Infirmary Lighting.—The Stockport Infirmary is to be lighted electrically.

Ingleton.—The local electric light company are pushing on with their electric lighting scheme, and it is expected that current will be available by the end of the summer. Water power is to be utilised, the turbines being supplied by Messrs. Gilbert Gilkes and Co., of Kendal. Of the £2,500 capital of the company, £2,000 has been subscribed locally. Gas is 6s. 8d. per thousand in this district.

Ilford.—The Council have adopted Mr. W. C. C. Hawtayne's scheme for the erection of electricity works, and tenders will shortly be invited.

Islington (London).—The Electric Lighting committee are to report upon the question of extending the electric light mains to Hornsey-road (to parish boundary), Stroud Green-road, Crouch Hill, Blackstock-road, Gillespie-road, Drayton Park, St. Paul's-road, Newington Green-road (to parish boundary on Newington Green), Mildmay-road, Mildmay Park, and Ball's Pond-road, and to submit estimates of cost. It is quite time these outlying portions of the parish were afforded an opportunity of adopting the electric light. Supply commenced in January, 1896.

Leyton.—According to a recent report by the electrical engineer (Mr. F. Harman Lewis) the capacity of the electricity supply station, when the extensions in progress have been completed, would be equivalent to 19,000 8 c.p. lamps, and as 13,000 lamps had been already connected, it was advisable to order additional plant at once, the cost of which was estimated at £24,086. He had obtained quotations from the makers of the most suitable kinds of engines, to be delivered and erected by 1st prox. next. Messrs. Willans and Robinson offered two 300 B.H.P. engines at £1,184 each, being £3·87 per brake horse-power. Each engine would supply 5,700 8 c.p. lamps. Messrs. G. E. Belliss and Co. offered two 350 B.H.P. engines at £1,429 each, being £4·08 per brake horse-power. Each engine would supply 6,500 8 c.p. lamps. In order to obtain any of the engines by the date named they must be ordered by the end of the month, and Messrs. Willans and Robinson, whose tender he recommended for acceptance, would take the order on the understanding that approval of the Local Government Board was subsequently obtained. This plant would be a portion of that for the general scheme of extension by steam, which he recommended should be of such size as to contain four 5,700 8 c.p. lamp engines. This would allow three for working purposes, and the capacity would be 17,000 lamps actual, at the consumers' terminals. Taking 60 per cent. as the ratio of the lamps actually supplied at maximum load to those connected to the mains, it would give the capacity of 28,300 lamps connected. The cost of the scheme would be approximately £24,086, and included four boilers, four engines, four dynamos, steam and exhaust pipes, pumps, tanks, &c., overhead crane, switchboard and connections, water softener, condenser, economiser or feed heater, buildings and foundations, mains, service lines, meters, terminal boxes, lamps, columns, &c. Having regard to the urgency of placing the order for two of the engines, the Electric Lighting committee have acted upon the recommendation of Mr. Lewis and placed the order, subject to the Council's confirmation. In addition to the £24,068, the purchase price of the land necessary for extensions would have to be provided for, and the committee recommended that application be made for sanction to a loan of £30,000 to carry out the extensions. The Council have adopted the report of the committee.

Light Railways.—The Board of Trade, on Friday, heard objections to the confirmation of the order granted by the Light Railway Commissioners for the construction of a light (electric) railway between Dundee and Broughty Ferry. The objectors were the Caledonian and the North British Railway Companies. Mr. Littler, Q.C., who appeared in the case, said he did not know why the promoters, who hailed from Leeds, should come marauding into Scotland to plunder the railway companies. The distance between Dundee and Broughty Ferry was about 3½ miles. The proposed light railway would not serve any new traffic, and it was a speculative scheme. Mr. Balfour Browne contended that under Sec. 9 of the Light Railways Act this order should not be confirmed. An application on behalf of the promoters for an adjournment till 29th inst. was agreed to.

The Hornsey Council have decided to apply for sanction to construct a light (electric) railway along the Archway-road to connect with the London County Council's system at the foot of Highgate Hill.

Light Railways along Main Thoroughfares.—In the House of Commons, on Tuesday, Sir J. W. Maclure asked the President of the Board of Trade whether his attention had been called to the issue of orders for the construction of light railways along main thoroughfares in populous districts; and whether he would consider the propriety of suspending any further orders until the opinion of the law officers of the Crown as to the legality of the action of the Board and of the Light Railway Commissioners could be ascertained. In reply, Mr. Ritchie said the Board of Trade were advised at the outset upon the legality of the course that had been adopted—a course which had now become well-settled practice.

Maidstone.—Electric lighting matters do not make much progress in this town. Reports from the Electric Lighting committee and the consulting engineers (Messrs. Kincaid, Waller and Manville) were considered at a recent meeting of the Council, but no decision was arrived at. The Maidstone provisional order was obtained in 1892.

Manchester.—According to the estimates of the Electricity committee for the current year an income of £82,500 is anticipated. After meeting all expenditure it is expected there will be a surplus balance of £8,115, and by adding £2,000 from last year, there will be

Digitized by Google

a total disposable balance for the year of £10,115, of which £10,000 will be paid to the city fund. In the year just closed there was an actual profit of £16,754, out of which £12,000 was paid to the city fund, the remainder being held over. The estimated expenditure on capital account for the year is £203,400, the principal items being Dickinson-street station £26,900, Bloom-street station £18,200, Stuart-street station £40,000, cable stores £10,000, and mains £86,200. For street lighting there is an estimate of £2,000. receivable from the city fund.

In the estimates of the Tramways committee an item of £3,000 figures for sample electric tramcars.

Mile End (London).—£30 has been voted by the Vestry to enable inquiries to be made as to the advisability of establishing electricity supply.

Mill Lighting.—The electric light is to be introduced into the Lucknow (India) Paper Mills. "Safety, economy and efficiency are the grounds upon which this decision has been arrived at." At present kerosene oil lighting is employed.

Municipal Trading.—The Plymouth Mercantile Association approves the proposed parliamentary inquiry to define the limits of municipal trading.

Newcastle-on-Tyne.—The Tramways committee recommend the Council to appoint a permanent electrical engineer at a salary not to exceed £500 per annum in order to supervise the construction of electric tramways under the consulting engineer, Mr. C. Hopkinson.

Oswestry.—Mr. W. C. C. Hawtayne has been retained by the Council to report on the advisability of purchasing the undertaking of the Oswestry Electric Light and Power Co.

Paddington (London).—No objection is to be made by the Vestry to the proposal of the Metropolitan Electric Supply Co. to lay electric light mains in Shirland and Croxley-roads and Saltoun-crescent. The company also propose to lay mains in a number of streets in the northern part of the parish.

Paignton (Devon).—The Council have appointed a committee to report upon a scheme submitted by a company for the electric lighting of the district.

Perth (W.A.).—Rapid progress is being made with the work of constructing the electric tramways in this town, and it is anticipated that the first section will be completed by July 1.

Private Bill Legislation.—The Charing Cross, Euston and Hampstead Railway Co. has been ordered for third reading in the House of Commons.

The Central London Railway Bill was read a third time in the House of Commons on Tuesday.

Opposition has been withdrawn to the Kensington and Notting Hill Electric Lighting Bill, and it will now go forward as an unopposed measure.

The House of Lords has passed the preamble of the Glasgow Corporation Tramways Bill, under which the Corporation seek powers to extend their tramways into a number of areas outside the municipal boundary. The Corporation have come to an agreement with the Paisley Corporation to acquire the tramways in Paisley three years hence, and the Glasgow Corporation will work the lines as well as the tramways running through Renfrew and connecting Glasgow with the Paisley system.

Ramsbottom (Lancs.).—The newly-elected chairman of the Council (Mr. J. Garnett) suggests that an electrical expert should be engaged to prepare an estimate of the probable cost of lighting the town electrically. He thinks an electric lighting scheme would prove remunerative.

Richmond (Yorks.).—The Council has recently discussed a report, prepared by Mr. A. A. Campbell Swinton, on the proposal to establish electricity works. Mr. Swinton points out that it is questionable whether sufficient support could be obtained for such an undertaking, and the Council has decided to postpone further consideration of the matter.

Ripley.—The advisability of erecting electric supply works is to be considered and reported upon by a special committee of the Council.

St. Pancras (London).—The Vestry have sanctioned an expenditure of £5,500 for a cable to connect up the Regent's Park and King's-road stations so that the latter may obtain current from the former in case of need.

Seville.—The entire tramway system of this city is being converted to electric traction. Heavier rails are being laid, and the lines are being largely extended. The plant and material are mainly German, the tramway company being a German concern.

Shoreditch (London).—The Vestry have decided, at the suggestion of Mr. C. Newton Russell, chief electrical engineer, to establish two new arc light circuits, each to comprise 20 lamps, at an estimated expenditure of £2,350. The Lighting Committee have been requested to further consider a proposal to obtain the arc lamp columns, lamps and switches from former contractors.

Soudan Telegraphs.—In the report on Egypt, by Lord Cromer, just issued from the Foreign Office, the following particulars respecting Soudan telegraphs are given :—

"The Soudan telegraph system south of Khartoum will be extended up the east bank of the Blue Nile to Abu Haraz. Thence a branch line will be carried to Gedarif, which will be connected with Kassala. A second line will run from Abu Haraz to Sennaar, the Blue Nile being crossed by means of a cable. From Sennaar the line will run to Abba Island on the White Nile, and thence up the river to Fashoda and the Sobat. These extensions will require about 1,000 miles of wire. The greater portion of the wire has been already sent to the Soudan. Work is proceeding on the Kassala-Gedarif section. An arrangement has been made as to the rates to be charged on through telegrams passing over the Soudanese and Egyptian lines in the event of telegraphic communication being established with South Africa."

Teddington.—The Council have unanimously decided to apply for a provisional order.

Telegraphs in East Africa.—The Belgo-German South Cameroons Co. has been amalgamated with the British Mozambique Co. in order to build a railway and erect a telegraph from Beira to the British possessions on the Zambesi. The company has a capital of 25,000,000f., with headquarters in Lisbon, and branches in London, Paris and Brussels.

Theft of Cable.—At the County of London Sessions on Saturday Mr. Loveland sentenced John Williams, James Smith and William Clark to 8, 4 and 12 months' imprisonment respectively for stealing a large quantity of electric light cable, value £170, from the Crystal Palace District Electric Supply Co.

The Government Telephone Proposals.—The Cardiff Chamber of Commerce decided on Wednesday to memorialise the Government against the Telephone Bill and in favour of a system with one central authority.

The Hyde Park Court Fire.—In connection with the fire which occurred at Hyde Park Court, London, this week (referred to in another column), Commander Wells, chief superintendent of the Metropolitan Fire Brigade, stated at an inquiry into the cause of this conflagration that had the "call" reached headquarters more promptly a large proportion of the property destroyed might have been saved. In this connection it is stated that few metropolitan buildings and not one metropolitan theatre possesses a "fire alarm," and that the ignorance of the general staff as to where one if wanted could be found is general. The *Daily Telegraph* points out that this is an important point for theatre managers to consider in order that this omission may be remedied.

Warrington.—The Council have instructed the town clerk to submit a tender for the wiring of the workhouse and to offer to supply electric current for lighting the building at 5d. per unit. The consulting engineer (Mr. A. H. Preece) has been authorised to proceed with the working drawings of the electricity supply works.

Woking.—The Council and ratepayers are to have the assistance of Major Cardew in dealing with the vexed question of electric lighting. The proposal to purchase the undertaking of the Woking Electric Supply Co. was recently rejected by the casting vote of the Chairman, and a meeting of ratepayers was held last week to consider the position. Major Cardew, who is a resident in the district, attended, and said he thought the present company had been somewhat harshly treated in regard to the light they supplied. He thought that for a small country station, and such a district as Woking, there was little to find fault with it. He held an inquiry the other day in a very much bigger place than Woking, where there had been a total cessation of supply during the greater part of October, owing to a large station being run with only one engine. If the Woking undertaking were purchased, there was a great deal of money for which no possible return could be expected, and there was a good deal of money required to put the whole thing into an up-to-date condition. They must negotiate, if they negotiated at all, with the idea of purchasing the whole of the mains and the station. Then they would have to face the Local Government Board, and he thought they would probably find a good deal of opposition, and apart from local opposition there would be the question for the Local Government Board to decide of whether they could allow the rates of Woking to be burdened in any way for works in another parish. Big Corporations like Manchester had got powers to supply neighbouring districts, but they could hardly compare Woking with Manchester. It was not as if they had a self-contained thing, or were applying for an order themselves, and starting from the beginning. He thought it would be undesirable to begin what, in his opinion, would be a fruitless negotiation. He considered the district was one in which the electric light ought, properly managed, to be a very great success, because they had a neighbourhood in which a good class of building was continually going on. As soon as people had confidence in the light, houses would be wired as a regular thing. A resolution in favour of opening fresh negotiations was carried, Major Cardew acting as scrutineer.

PATENT RECORD.

The following list of Applications for Patents and Specifications published has been compiled for this journal by Messrs. J. C. CHAPMAN and Co., *Chartered Patent Agents, of 70, Chancery-lane, W.C., from whom any available information in connection with Patents, Designs and Trade Marks may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned Applications are not open to public inspection until after the acceptance of the complete Specification. The names within parentheses are those of communicators of inventions. When complete specification accompanies application an asterisk is affixed.*

March 10, 1899.

5,250. C. W. HILL. Oldham. Automatic electric brake.
5,255. R. F. HALL. Birmingham. Improvements in electrical switches.*
5,262. R. F. HALL. Birmingham. Improvements in electrical tumbler and other switches.
5,279. J. A. L. DEARLOVE. London. Improvements in electric cables.
5,296. G. S. FORT and A. FORT. London. A method of distinguishing electric and other switches in the dark.
5,322. J. H. LAMPREY. London. Improvements in or in connection with apparatus for the production of ozone by electricity.

March 11, 1899.

5,341. A. WATSON. Birmingham. Improvements in tumbler switches for electrical purposes.
5,356. H. BENNETT. Keighley. Improvements appertaining to electric arc lamps.
5,374. J. J. STANGER. London. Improvements in and relating to electro-therapeutic bath and the like.*
5,392. H. A. EARLE. London. Improvements in controlling switches for electric motors.
5,398. E. BEDE. London. Improvements connected with electric traction.*

March 13, 1899.

5,416. J. J. WALKLATE. Birmingham. Improvements in spring break switches for electric currents.
5,464. P. SCHARF. London. Means for rendering electrically conductive incandescence bodies which conduct only when their temperature is raised and apparatus therefor.
5,468. A. ZIMMERMANN. London. Improvements in the electro-deposition of metals. (Dr. Courant, Germany).

March 14, 1899.

5,486. G. C. ALLINGHAM and W. FENNELL. London. Improvements in electric incandescence lamps.
5,514. G. W. MORGAN. Aberdeen. Improved electric light apparatus for taking photographic portraits.
5,518. T. B. KINRAIDE. London. Improvements in electric spark gap apparatus.*
5,519. T. B. KINRAIDE. London. Improvements in electric break apparatus.*
5,543. B. S. COHEN and P. H. COLE. London. A multiplex selective system of "wireless telegraphy."

SPECIFICATIONS PUBLISHED.

NOTE.—All Specifications can now be obtained at the uniform price of 8d. each.

1898.

6,633. COOKE and IRELAND. Apparatus for indicating the charge in a secondary battery.
7,199. TATE. Wall socket and plug for electrical fittings.
7,283. HARRISON. Miners' lamps and apparatus for electrically lighting the same.
7,333. MÉRIAN. Construction of plates for electrical accumulators or storage batteries.
7,470. WISE (Solvay and Co.). Effecting electrolysis.
7,471. WISE (Solvay and Co.). Electrolysis.
8,054. MOORES and FARRELL. Means for fixing or fitting incandescent electric lamps into lanterns.
8,140. WRIGHT. Switches for electric circuits. (Date applied for under International Convention, September 18, 1897.)
8,142. LAMME. Systems of electrical distribution. (Date applied for under International Convention, Sept. 18th, 1897.)
8,348. HEAP. Electrical measuring and indicating instruments.
8,391. DAVIS. High-tension transformers and induction coils for Röntgen ray work and for other purposes.
9,002. BROCK and THE UNITED ALKALI Co. (LIMITED). Apparatus for the manufacture of potassium, chlorate, or sodium chlorate by electrolysis.
10,428. MARTIN. Electro-therapeutic exercising apparatus.
10,710. WEISS. Dry battery.
11,858. KING. Manufacture of elements or plates for secondary batteries or electric accumulators.
12,313. KING Secondary batteries or electric accumulators.
13,569. BARKER. Jointing electric cables.
14,548. BOWLES. Electrical contact makers.
15,801. LEIMER. Electric accumulators.
15,802. LEIMER. Electric accumulators.
18,552. CAPEWELL. Motor-trucks for electric and other railways or tramways, and driving gear therefor.
19,824. COTTERELL. Means or apparatus for facilitating calculations relating to secondary electrical batteries.

COMPANIES' MEETINGS AND REPORTS.

The Consolidated Telephone Construction and Manufacturing Co. (Limited).

The adjourned extraordinary meeting of this Company was held yesterday (Thursday) to continue the business adjourned from August 18 last and to consider a report made by the committee then appointed. Mr. C. L. W. FITZGERALD presided.

The CHAIRMAN referred to the question of proxies and to the issue of the report, and said that no doubt a member of the committee would make some remarks.

Mr. W. R. LAWSON (a member of the committee) stated that on behalf of the committee proxies had been sent in favour of their report representing 63,000 shareholders, while the proxies obtained by the Chairman represented only 40,000. They would remember that at the meeting last August the Directors suddenly and unexpectedly brought forward a proposal that the Company should be wound up voluntarily. The shareholders declined to act on this suggestion, and appointed a committee which had held many meetings, and, with the assistance of two of the Directors, had obtained a considerable amount of information as to the working of the Company during the past few years. At a very early stage it began to be evident that if the Company were to survive at all, the management would have to be very considerably changed. After several failures the committee got into communication with a gentleman of technical knowledge, Mr. Hubert Jackson, whom they all agreed in regarding as highly suitable for serving the Company. It had seemed to the committee that there was not only a great want of expert management in the Company, but also considerable room for more business management. The committee, therefore, proposed that two of the Directors, who had endeavoured to keep the existing management right, and were not always agreed with the Chairman, should remain, and that room should be made for two new Directors. That was the whole business before the meeting now. He concluded by moving a resolution, "That the committee's report be adopted, and that the voluntary winding up proposed by the Directors was unnecessary."

Mr. F. C. STOOP seconded the motion.

The CHAIRMAN said he was accused of mismanaging the business. His colleagues took the management out of his hands in 1892. That being the case why did not the whole Board resign, and why should he be personally attacked? He had done his best for 15 years for the shareholders, and had sacrificed he did not know how many thousands of pounds in connection with the Company. He honestly believed that the Board had done their utmost to serve the interests of the shareholders. The committee's report and letter reached the shareholders on April 7; there was a Board meeting on the 10th, and his reply was in the hands of the shareholders on the 15th. Through Mr. Grewing and Sir Alexander Armstrong, the committee pressed him so hard to fix the date of a meeting, before their report came out, that at last he did so, and on March 24th the present meeting was fixed. The committee's report, however, was ready on March 15th. Why was its issue delayed? While the committee had been squabbling the Directors had been making money, and that without any recommendations of the committee being carried into effect. It seemed to him that what he had proposed in the course of his reply would be the much better course to take. He might state that he had strongly objected to their electrician leaving them. It had been said that it was he who nominated Mr. Menzies as general manager, but that was not the case, as shown by the resolution of the Board, which was in his circular. He asked the shareholders whether it was not strange that the Company was in such good order if there had been the lax management which had been suggested by the committee. All that the Company wanted was orders. Apart from the question of the Directors, the Committee's report amounted to this:—Appoint an electrician, appoint a works manager, get a traveller. His (the Chairman's) proposal was exactly to the same effect. He believed that a new era had dawned in the telephone world. The Post Office were going to compete with the National Company, and that was a fact which altered everything. It did not matter to him if the shareholders chose to dispense with his services, although he was willing to serve them if they desired it.

After a few remarks from Mr. DRUCKER,

Mr. A. H. BAKER said the committee stated that when the meeting was called for August 18 the proposal of the Directors was to wind up the Company, but he (the speaker) emphatically denied this. Acting under a promise given to Mr. Stoop, with the pressure of Mr. Grewing, that meeting was called. The competition was then so keen and so great on the part of foreigners, who were not trammelled by trades unions, that the Company were practically making no money, and the Directors honourably and straightforwardly, as trustees for the shareholders, brought the question of liquidation before the latter; but he was at a loss to understand how Mr. Stoop and Mr. Lawson could state that the Directors suggested the liquidation of the Company. The prime mover for winding up the Company was Mr. Stoop, whom the Directors had fought, and whom they would continue to fight if they remained on the Board. Since August 18 the Postmaster-General had given his consent to competitive telephones in municipalities. The whole state of matters had thus been altered. There would now be an enormous demand for telephones, although he could not say whether the demand would be at prices profitable for the company. The reason why the Directors brought the shareholders together last August had now passed away. He was strongly against the liquidation of the Company, owing to the change that had taken place, and he looked forward to there being some return for the shareholders. The committee stated that the Company had not a standard telephone, but

Digitized by Google

who were their customers? The Post Office and the large railway companies, and when they tendered for work which they required done for them, the Company manufactured the article they required.

Mr. WOOLLEY supported generally the action and recommendations of the committee.

Mr. BAKER said a resolution for the liquidation of the Company had never been before them.

Col. WEST moved an amendment: "That the report of the committee be received and their suggestions carried out in the mode proposed by the Chairman in the first five paragraphs on p. 4 of his circular" (which was before the meeting).

This was seconded and further discussion followed. Eventually the Chairman put the amendment, in favour of which 10 voted for and 11 against. He afterwards put the original motion, for which 11 voted for and 6 against.

The proceedings then terminated.

Eastern Extension, Australasia and China Telegraph Co. (Limited).

The report of the directors of this company, for the half-year to Dec. 31 last, states that the gross receipts have amounted during the half-year to £290,431 1s. 9d., against £275,142 7s. 2d. for the corresponding period of 1897. The working and other expenses, including £26,045 1s. 7d. for cost of repairs to cables and expenses of ships, absorb £100,085 18s. 5d. against £102,844 13s. 10d. for the corresponding period of 1897, leaving a balance of £190,345 3s. 4d. From this is deducted £4,698 19s. for income tax, £31,921 5s. for interest on debentures, debenture stock, and contribution to sinking fund, &c., leaving as net profit £153,724. 19s. 4d., which, with £10,723. 1s. 9d. brought forward, gives an available balance of £164,448. 1s. 1d. One quarterly interim dividend of 1½ per cent. has been paid for the half-year, and it is now proposed to distribute another of like amount on 27th inst., making, with interim dividends, a total dividend of 5 per cent. It is also proposed to pay a bonus of 4s. per share, or 2 per cent., making a total distribution of 7 per cent. for the year 1898. The balance of £51,948. 1s. 1d. has been transferred to general reserve.

The policy of gradually renewing weak portions of the company's system has been steadily pursued. The cost of the renewals, amounting to £56,805. 12s. 1d., has been charged against general reserve.

Having been advised that, according to International Law, the United States are bound to take over the obligations which Spain entered into with the company in regard to telegraphic communication in the Philippines, the necessary representations have been made through diplomatic channels to the Government of the United States on the subject.

The development of the insurrection in the Philippines having made it impossible to maintain efficient telegraphic communication, the company were for a short time compelled to close all their stations in the islands of Panay, Negros and Cebu, and withdraw the staff to Manila. Since the close of the year the Panay-Negros cable has been re-opened for public traffic, and, by arrangement with the Government of the United States, the company's Manila-Capiz cable has been extended to Ilo-Ilo direct, thus making the latter communication independent of the unsatisfactory land-lines between Capiz and Ilo-Ilo.

Cuba Submarine Telegraph Co. (Limited).

The report of the directors for the half-year ended Dec. 31 states that the receipts were £27,483. 17s. 11d., and the expenditure £7,585. 1s. 9d., leaving £19,898. 16s. 2d., which, added to the balance of £3,713. 11s. 6d. from last account, leaves £23,612. 7s. 8d. to credit of revenue. The traffic receipts show a considerable increase, compared with the corresponding period of last year, owing to the exceptionally heavy Government traffic consequent on the Spanish-American war. £10,000 has been added to reserve, which now stands at £120,000. The dividend on the Preference shares will absorb £3,000, and leave £10,612. 7s. 8d., out of which the directors recommend a dividend at the rate of 6 per cent. per annum, and a bonus of 2s. per share on the Ordinary shares, both free of tax, the balance (£4,212. 7s. 8d.) being carried forward.

At the date of the last report, the cables broken during the war had been repaired, with the exception of the Cienfuegas-Casilda cable and the 1891 cable between Cienfuegas and Batabano. The repairs to these have been completed during the current half-year, and the cost of the whole will form the subject of a claim against the United States Government, which will be put forward as soon as the accounts have been prepared.

Oriental Telephone and Electric Co. (Limited).

The directors' report for the year ended Dec. 31 states that revenue shows a credit balance of £10,955. 3s. 9d. transferred to profit and loss. Including £964. 8s. 3d. brought forward, and after deducting £2,858. 8s. the amount of interim dividend paid in November last, there remains £9,061. 4s. for disposal. The directors propose to pay a final dividend of 8d. per share, free of tax, making 5 per cent. for the year, to transfer £2,000 to reserve, and carry forward £1,344. 8s.

With regard to the Indian subsidiary companies, the Bombay Company has again paid 6 per cent. for the year, whilst the Bengal Company has paid 5 per cent., against 7 per cent for the previous year, carrying forward Rs.20,000 as a precautionary measure against possible temporary outlay. The Telephone Company of Egypt has declared its usual dividend of 6 per cent. on its Preferred shares. This Company has recently entered into an agreement with the Government of Egypt to continue the Government Telephone service for a period of 25 years from Jan. 1 last. Its business in general progresses favourably. The China and Japan Telephone Co. has paid its Debenture interest, but its accounts for the past year have not yet been audited. They point, however, to a larger surplus than in previous years.

With a view to improving the telephone service at Shanghai, which would have involved a large expenditure of money, the directors approached the Council of the Shanghai Settlements some years ago to obtain, if possible, a prolonged term of concession so as to justify the outlay. The Council has now decided to grant a 30 years' concession, but has invited tenders by public advertisement. The directors of the China and Japan Co. have sent in a tender, but the result so far is not known.

The electric lighting branch of the Company's business shows a small surplus, which has been carried meantime to a suspense account to provide for expenses in connection with a change of management now being proceeded with in Calcutta.

Submarine Cables Trust.

The report of the trustees for the financial year to April 15 states that the revenue, including balance of £20. 3s. brought forward, amounted to £21,476. 2s. 3d. Expenses amounted to £1,108. 10s. 6d., and payments on account of coupons £20,286 (together £21,394. 10s. 6d.), leaving £81. 11s. 9d. to be carried forward.

The Brazilian Submarine Telegraph Co. (Limited), having entered into an arrangement with the Western and Brazilian Telegraph Co. (Limited), offered some of their shares in exchange for those of the latter company, held by the trust on the basis of five Ordinary shares of £10 each in the Brazilian Company for every six Ordinary shares of £15 each in the Western and Brazilian Company, and the trustees decided to assent to the proposed exchange, which has since been carried into effect. Certificate holders will be asked to confirm the resolution and sanction such exchange.

EDWARDS' PUMP SYNDICATE (LIMITED).—At the meeting on Tuesday Mr. C. W. Milne said they were on the eve of a tremendous development in electrical engineering, and it was satisfactory that no pump in the market that they knew of was better than theirs for running at high speeds. Conversations with electrical engineers had convinced them that when the time came their pump would meet with great favour. In some of the largest corporation electrical installations their pump had been specified for.

GREAT NORTHERN TELEGRAPH CO. (LIMITED).—The gross receipts for the year 1898 of this Company amounted to £402,795. 16s. 3d. After deducting £23,474. 14s. 9d., loss on exchange, and including a balance forward of £61,057. 17s. 10d., the total revenue account for the year was £463,850. 14s. 1d. Working expenses, &c., amounted to £85,130. 17s. 5d., leaving £378,722. 10s. 8d. An interim dividend of 10s. per share was paid absorbing £75,000, and a final dividend is now proposed of 15s. per share absorbing £112,500. £116,666. 13s. 4d. is added to reserve and renewal fund, £3,888. 17s. 9d. to the staff pension fund, and £61,417. 5s. 7d. is carried forward.

NATIONAL ELECTRIC FREE WIRING CO. (LIMITED).—At a confirmatory meeting of the shareholders held at the offices on Wednesday the resolution set out in our issue of March 31 altering the name of the company to the "National Electric Wiring Co. (Limited)" was approved.

WOODLANDS ELECTRIC CO. (LIMITED).—The first annual meeting of this company was held on Monday, when dividends were declared at the rate of 6 per cent. upon the Preference and 1½ per cent. upon the Ordinary shares.

NEW COMPANIES, STATUTORY RETURNS, &c.

ADAMS-RANDALL TELEPHONE PATENTS (LIMITED).—This company was registered on April 11, with a capital of £60,000, in £1 shares (of which 10,000 are £6 per cent. Cumulative Preference), to enter into an agreement with Mr. Charles Adams-Randall, to acquire, develop, work and deal with certain patents, and to carry on the business of a telephone, telegraph and electric light, heat and power supply company. The first subscribers (with one share each) are:—J. C. Hulbert, W. H. Parker, E. J. Broadbent, W. Lloyd, J. C. Colledge, J. S. Hall, and T. G. Holloway.

COMPASS TRADING CO. (LIMITED).—This company was registered on April 14 with a capital of £5,000, in £1 shares, to acquire the business of an engineer, general and financial agent and contractor, carried on by Mr. Edward Mann, and to carry on the business of general engineers, contractors, telegraph, telephone, electric light and engine makers, manufacturers of electrical apparatus, &c. The first subscribers (each with 100 shares) are:—C. A. Rollason, W. H. Fletcher, A. W. Paul, E. T. Pimm, E. J. Hale, G. R. Rollason and William F. Fearn. The first directors are:—Edward Mann, W. H. Fletcher, and one to be nominated by the subscribers.

HEATON AND SMITH (LIMITED).—This company was registered on April 14th with a capital of £25,000, in £10 shares, to acquire and carry on the business of electrical engineers and manufacturers of electrical apparatus carried on under the style of Heaton, Smith and Co. The first subscribers (with one share each) are:—F. W. Heaton (electrical engineer), H. Smith (electrical engineer), J. Eades, R. Heaton, T. L. Marsden, J. A. Shaw, and R. Watkinson. The first directors are the first three subscribers.

LANCASHIRE DYNAMO AND MOTOR CO. (LIMITED).—This company was registered on April 11, with a capital of £100,000, in £100 shares, to carry on the business of mechanical, electrical and hydraulic engineers, manufacturers of machinery, tool and boiler makers, metal founders and workers, and to manufacture, buy, sell, let and deal in apparatus and appliances of all kinds used in connection with the generation, distribution, supply, accumulation and employment of elec-

Digitized by Google

tricity. The first subscribers (with one share each) are:—N. Kilvert, H. V. Kilvert, A. Tongue, W. Cherry, E. Pilkington, W. W. Pilkington, and A. P. Wood. The first directors are:—N. Kilvert, H. V. Kilvert, W. Cherry, and A. Tongue.

VAUGHAN AND SON (LIMITED).—This company was registered on April 15 with a capital of £50,000, in £1 shares, to carry on the business of mechanical and electrical engineers, machinists, tool makers, and manufacturers of and dealers in all kinds of cranes and hoisting apparatus actuated by electricity, steam, or other power, dynamos, electric motors, all kinds of electrical apparatus, engines, boilers, &c. The first subscribers (each with one share) are: William H. Vaughan (engineer), John T. Vaughan (engineer), T. Foster (engineer), J. Markham, Mrs. E. Markham, Mrs. G. T. Sadler, Miss H. Vaughan. The first directors are:—William H. and John T. Vaughan and T. Foster.

BIRMINGHAM ELECTRIC SUPPLY CO. (LIMITED).—According to the annual return to March 22, the whole nominal capital of £200,000, in £5 shares, has been taken up and paid for in full.

BRITISH COLUMBIA ELECTRIC RAILWAY CO. (LIMITED).—The annual return to Aug. 8, 1898, was filed on Feb. 14, when 20,007 shares were taken up out of a capital of £250,000, in £10 shares. 20,000 are considered as fully paid, and 5s. per share has been called and paid on the remaining seven shares.

BRITISH COLUMBIA TELEPHONES (LIMITED).—The statutory return to Feb. 7 has been filed. The capital is £100,000, in £10 shares (of which 3,000 are Preference). 2,000 Preference and 3,000 Ordinary shares have been taken up, and the full amount has been called on the former, while £7. 10s. per share has been called on the latter.

NORWICH ELECTRICITY CO. (LIMITED).—The annual return to March 16 has been filed. The whole nominal capital of £50,000, in £10 shares, has been taken up and paid for in full. The capital has since been increased to £100,000 in £10 shares.

CITY NOTES.

MEMORANDA.—Bank rate 3 per cent. (since Feb. 2, 1899). Price of silver 27⅜d. per oz. (April 20). Consols (2¾ per cent.) 110½—110¾ for money, 110$\frac{11}{16}$—110$\frac{13}{16}$ for account; 2½ per cent. 103⅜—103⅝ (April 20), Stock Exchange Settling Days: Consols, May 4; Stocks and Shares Continuation Days, April 25 and May 10; Ticket Days, April 26 and May 11; Pay Days, April 27 and May 12; Mining Share Carry over Days, April 24 and May 9.

ANGLO-ARGENTINE TRAMWAYS CO. (LIMITED).—A meeting will be held to-day (Friday) to approve an agreement for the conversion of the existing horse tramways into overhead trolley lines.

SOCIETE ANONYME L'ACCUMULATEUR SEC.—An ordinary general meeting of this company will be held at Brussels on May 4.

STOCK EXCHANGE NOTICES.—The Stock Exchange committee has appointed Wednesday, the 26th inst., a special settling day for £233,334 First Mortgage Four per Cent. irredeemable Debenture stock of *Doulton and Co. (Limited)*. The Committee has been asked to allow this stock and 233,334 Five per Cent. Cumulative £1 fully paid Preference shares (Nos. 516,667 to 750,000) in the same company to be quoted in the official list. The Committee has also been asked to appoint a special settling day in 29,935 £5 vendor's Ordinary shares (fully paid), and a further issue of 40 £5 fully paid Ordinary shares in the *British Insulated Wire Co. (Limited)*, and to appoint a settling day in and to grant a quotation to 50,000 £1 Ordinary and 60,000 Six per Cent. £1 Cumulative Preference shares in *Davis and Timmins (Limited)*.

WEST INDIA AND PANAMA TELEGRAPH CO. (LIMITED).—The estimated traffic receipts of the Company for the half month ended April 15 are £2,141, compared with £2,541 in the corresponding period of 1898.

JANDUS JANDUS

IMPORTANT ANNOUNCEMENT.

LARGE REDUCTION IN PRICES.

Owing to the extended use of labour-saving machinery and the manufacture on a larger scale, it has been found possible to issue the well-known JANDUS ARC LAMPS at a considerable reduction. The Lamps will have the same durable mechanism and cases, which it is claimed will outlast all the flimsy foreign imitations, and every effort will be made to maintain the reputation of the Jandus as "THE ENGINEER'S LAMP"

APPLY FOR FULL PARTICULARS TO THE SOLE AGENTS—

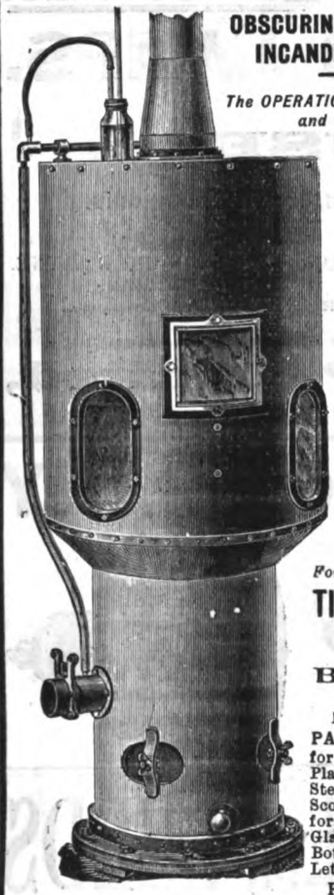
IMPROVED SAND BLAST APPARATUS

FOR

OBSCURING, DECORATING, and MARKING INCANDESCENT ELECTRIC LAMPS.

The OPERATION is RAPID, CLEANLY, and EFFECTIVE and NOT INJURIOUS TO HEALTH.



For further particulars apply to the Maker

TILGHMAN'S PATENT SAND BLAST CO., LTD.,

BROADHEATH,

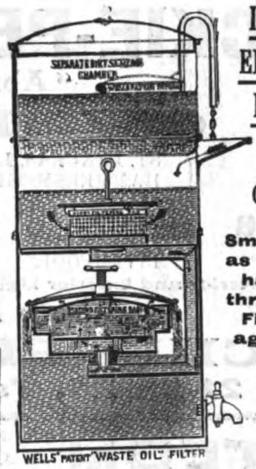
Near MANCHESTER.

Manufacturers of all descriptions of PATENT SAND BLAST APPARATUS for Removing Scale from Iron and Steel Plates, Bars, Forgings, &c.; Cleaning Iron, Steel and Brass Castings; Sharpening and Scouring Files; Frosting, Marking, Perforating, and Decorating Sheet and Plate Glass, Table Glass, Globes and Chimneys, Bottles, &c.; Cutting Ornaments and Letters on Granite, Marble, &c., &c.

FILE DEPARTMENT, SHEFFIELD.

WELLS' PATENT "WASTE OIL" FILTERS,

OVER **3,000** SOLD.



INVALUABLE to ELECTRIC LIGHT INSTALLATIONS and ALL USERS of MACHINERY.

Small Money Savers, as Dirtied Oil which has hitherto been thrown away can be Filtered and used again and again.

Write for Descriptive Price List and Samples of work done by the Filter.

A FEW OUT OF MANY TESTIMONIALS RECENTLY RECEIVED.

"We are very well pleased with your Waste Oil Filter. Our engineer says that he obtains more than half a gallon (nearly three-quarters) of good oil from every gallon of dirty oil put into the Filter, and, as this dirty oil was always thrown away before we had your Filter, you can judge of the saving."

"Your Filter is working wonders. The used oil comes out perfectly cleaned. We do not use a big quantity of oil, but we are quite sure it will save its cost in a very short time. Any firm possessing a Gas Engine would find it very economical."

"We have pleasure in stating we are pleased with the Oil Filters, which are well finished and perform their work satisfactorily. Nearly all the Gas Engines and Dynamo Plants we have put down have your Filters, and use the same oil time after time."

No. 1.—For users having small quantities (no syphon), 17in. by 9in. ... **35s.**
No. 2.—Two top chambers hold 3 gallons, a useful size, 22in. by 10in. **50s.**
No. 3.—Two top chambers hold about 6 gallons of oil, 27in. by 12in.... **70s.**
No. 4.—Powerful Filter for treating large quantities of oil; two top chambers hold about 12 gallons of oil, 36in. by 16in. ..... **110s.**
No. 5.—A powerful Filter, two top chambers hold 24 gallons, 43in. by 23in. ..... **189s.**

"THE ELECTRICIAN"

ELECTRICAL TRADES' DIRECTORY

AND HANDBOOK

(Established 1882.)

For 1899

(*Tho Big Blue Book*)

Is in **Active Preparation,** and the various Circulars and Particulars relating to the New Issue will reach members of the Profession and the Trade generally by the end of November. In order to ensure correctness and completeness, it is, of course, essential that the process of compilation of the DIRECTORIAL SECTION should be deferred to as late a period in the year as possible—that is, if correctness and completeness is the aim, and not a mere list of names and addresses, good, bad and indifferent.

ADVERTISERS are reminded that the **Big Blue Book** is the Leading and Only Reliable work of reference for the entire group of Industries associated with Electrical Enterprise throughout the world, and the 1899 Edition will contain several New and Novel Features, which will serve to render the **Big Blue Book** more than ever the indispensable Handbook for the Consulting, Contracting, and Manufacturing Electrical Engineer, and the Reliable Office Companion of the Wholesale and Retail dealer in all kinds of Electrical Manufactures.

For Indicating the Temperature in Hotels, Ships, Clubs, Cold Stores, &c. A PERFECT ALARM!

HICKS'S
PATENT
BATTERY HYDROMETERS.

Full Particulars on Application.

FIG. 1 has four different coloured beads, indicating different gravities, and the correct gravity is shown on the bead which floats nearest the centre of the tube. It has a hooked top, so that it may hang inside the accumulator, and is excessively simple and absolutely reliable.

Price only 4s. 6d.

FIG. 2 is loaded with shot at one end, and has the scale clearly marked in its stem. It is made to float in the battery, and is in extensive use by Electric Companies.

Price 2s.

FIG. 3. This beautiful Instrument (designed by Mr. Keating) has a pure white enamel glass stem, which is open at the top, and there is a hole at the bottom of the stem through which the fluid enters as it sinks in the test jar. It therefore differs materially from all other Hydrometers, and gives such a splendid *open scale* that reading is rendered exceptionally easy and distinct.

Price 4s. 6d.

TENDERS INVITED.

HORNSEY URBAN DISTRICT COUNCIL.

TO ELECTRICAL ENGINEERS AND OTHERS.

The HORNSEY URBAN DISTRICT COUNCIL are prepared to receive TENDERS for the SUPPLY of ELECTRIC LIGHTING PLANT and its ERECTION at the Council's Central Public Library, situate in Tottenham Lane, Hornsey.

Specifications and Forms of Tender, and all information, can be obtained on application to Mr. E. J. Lovegrove, Engineer to the Council, at the Offices mentioned below, on any morning between the hours of 10 and 12 o'clock, on a sum of Two Pounds being deposited with the Clerk to the Council, which sum will be retained by the Council and deemed to be forfeited if a bona fide Tender is not made by the depositor.

If a Tender is made which is not accepted the sum deposited will be returned, and if a Tender is accepted such sum will be retained by the Council until the contract has been executed by the depositor, and will be forfeited in the event of his or his sureties failing or neglecting to execute such contract or the bond accompanying the same within seven days after he or they respectively shall have been requested to execute the same.

No Tender will be considered except on the prescribed Form.

Sealed and endorsed Tenders to be deposited in the Tender-box in my Department not later than 4 o'clock p.m. on MONDAY, the 7th day of November, proximo.

The Council reserve to themselves the right to decline all, or any portion, of the Tenders so sent in.

By order,
F. D. ASKEY, Clerk to the District Council.

Offices: Southwood-lane,
Highgate, N., 25th October, 1898.

BOROUGH OF MIDDLESBROUGH.

MUNICIPAL ELECTRICITY SUPPLY UNDERTAKING.

LOW TENSION SYSTEM.

The ELECTRIC LIGHTING COMMITTEE of the BOROUGH of MIDDLESBROUGH are prepared to receive TENDERS for the SUPPLY and ERECTION of the following PLANT:—

Section A.—BOILER HOUSE PLANT: Lancashire Boilers and Accessories, Mechanical Stokers, Feed Pumps, Injector, Economiser, Electric Motor.
Section B.—ENGINE HOUSE PLANT: Slow Speed Steam Dynamos and Accessories.
Section C.—CONDENSING PLANT and PIPEWORK.
Section D.—OVERHEAD TRAVELLING CRANE.
Section E.—SWITCHBOARD and INSTRUMENTS.
Section F.—ACCUMULATORS.
Section G.—UNDERGROUND WORK: Trenching, Cables, &c.
Section H.—METERS.

The whole bound up in one Specification. Applicants must state for which Section or Sections they wish to tender, in order that the requisite drawings may be forwarded to them.

Tenderers are at liberty to tender for any Section, but not for part of a Section.

Specifications, with Terms and Conditions and Forms of Tender, may be obtained at the Offices of Mr. Robert Hammond, M.I.E.E., the Consulting Engineer to the Borough, 64, Victoria-street, Westminster, S.W., on and after Wednesday, November 2nd, 1898, on payment of £5. 5s., which sum will be refunded on return of the Specification filled up with a bona fide Tender. Duplicate copies of the Specification £1. 1s. each, not returnable.

Tenders, sealed and marked "Tender for Electricity Works," must be addressed to me at the Municipal Buildings, and be delivered on or before TUESDAY, November 29th, 1898.

The Committee do not bind themselves to accept the lowest or any Tender.

GEORGE BAINBRIDGE, Town Clerk.

Middlesbrough, October 27th, 1898.

BELFAST HARBOUR.

The BELFAST HARBOUR COMMISSIONERS are prepared to receive TENDERS for the SUPPLY of NINE IRON LATTICE-BUILT ELECTRIC LIGHT MASTS, 70ft. high from the ground-line, with suitable base.

Parties tendering must submit drawings to scale giving full particulars of the construction of the Masts and state the earliest date within which they will undertake to deliver the same.

The Masts to be delivered free of all charges on the Quay at Belfast.

Sealed Tenders to be addressed to the undersigned, endorsed, "Tender for Electric Light Masts," and sent in on or before MONDAY, November 14, 1898.

The Commissioners do not bind themselves to accept the lowest or any Tender.

W. A. CURRIE, Secretary.

Harbour Office, Belfast.
October 26, 1898.

The Liquidator of the above named Company invites TENDERS for the PURCHASE of the undermentioned PATENTS for Secondary Generators, belonging to the said Company;

No. 13,333, for Great Britain, dated 1st Oct., 1887, expiring 1901.
No. 18,355, for Great Britain, dated 16th Nov., 1889, expiring 1903.
No. 189,840, for France, dated 9th April, 1888, expiring 1903.

Specifications of the said Patents can be inspected, and further information obtained, on application to the Liquidator, as under, or to Messrs. Campbell Reeves and Hooper, 17, Warwick-street, Regent-street, London, W., the Solicitors to the Liquidator.

Tenders, addressed to the undersigned, will be received up to 12 o'clock on MONDAY, the 28th day of November, 1898.

The Liquidator does not bind himself to accept the highest or any Tender.

Dated this 26th day of October, 1898.

J. H. THORNTON, Liquidator.

2, Warwick-street, Regent-street,
London, W.

COUNTY BOROUGH OF SALFORD.

The ELECTRIC LIGHT COMMITTEE of the above CORPORATION are prepared to receive TENDER for the SUPPLY and ERECTION of the following PLANT:

Sections.	Sections.
1. BOILERS	8. CONDENSERS, &c.
2. ENGINES	9 STEAM & WATER PIPES
3. DYNAMOS	10. CRANES & WEIGHING MACHINES
4. BOILER FEED PUMPS, &c.	11. TANKS, &c.
5. MECHANICAL STOKERS	12. SWITCHBOARDS
6. SUPER-HEATERS	13. BOOSTER
7. ECONOMISERS	

Contractors may tender for one or any number of complete sections.

Specification, with Tender Forms and any further information, may be obtained from the Electrical Engineer, Walness-road, Broughton, on payment of £5, which sum will be refunded on receipt of Specification with bona fide Tender.

Sealed Tenders, endorsed "Electric Plant," and addressed to the Chairman of the Electricity Committee, to be delivered at my office not later than the 1st day of December, 1898.

By order,
SAML. BROWN, Town Clerk.

Town Hall, Salford,
October 25th, 1898.

COUNTY BOROUGH OF BARROW-IN-FURNESS.

ELECTRICITY SUPPLY.

CONTRACT No. 4.

The CORPORATION of BARROW-IN-FURNESS invite TENDERS for the SUPPLY and ERECTION of CAST IRON LAMP COLUMNS, ARC and INCANDESCENT LAMPS, AUTOMATIC SWITCHES and FITTINGS.

Specifications and Forms of Tender can be obtained from the Municipal Offices, Barrow-in-Furness, or at the Offices of the Engineers, Messrs. Kincaid, Waller and Manville, 29, Great George-street, Westminster, on payment of a fee of £3. 3s., which sum will be returned on receipt of a bona fide tender. The contractor will be required to pay not less than the minimum standard rate of wages, for the time being, in each branch of the Trade.

The Corporation do not bind themselves to accept the lowest or any Tender, and the contractor whose Tender is accepted shall enter into a formal agreement, under seal, with sufficient sureties for the due fulfilment of his Contract.

Sealed Tenders, endorsed "Electricity Supply Contract No. 4," must be sent to me at or before noon on MONDAY, the 14th November, 1898.

C. F. PRESTON, Town Clerk.

Municipal Offices, Barrow-in-Furness,
October, 1898.

REDDITCH URBAN DISTRICT COUNCIL.

The above COUNCIL are desirous of obtaining for the customers of the Municipal Electric Lighting Supply, the SERVICES of some FIRM of CONTRACTORS who will carry out WIRING and FITTING WORK for the inhabitants of the district, on some hire-purchase or deferred payment system, to spread the cost of wiring over a considerable period, not longer than seven years.

Applications and proposals with reference to this matter to be made to

J. A. McMULLEN, M.I.E.E.,
Hornchurch, Essex.

APPOINTMENTS VACANT.

COUNTY BOROUGH OF SALFORD.

ELECTRICITY DEPARTMENT.

WANTED, competent man as SWITCHBOARD ATTENDANT; wages 34s. per week.

Applicants must state age, experience, where last employed, and when able to commence duties. Man used to running alternators in parallel preferred. Applications, accompanied by not more than three recent testimonials, to be addressed to the Electrical Engineer, Electricity Works, Walness-road, Salford.

By order,
SAML. BROWN, Town Clerk.

Town Hall, Salford,
October 24th, 1898.

NOTICE.

P. R. JACKSON & CO., Ltd., desire to state that their New Arc Lamps (Jackson-Mensing Patents) are now Ready for Sale, and that Price Lists and Full Particulars will be furnished on application. The Lamps are equally Steady and Efficient on either Alternating or Direct Current Systems. Great care has been taken in their development, and they are offered with every confidence as being thoroughly sound and substantial. There is an entire absence of clockwork, or of cork, rubber or other vegetable material—features which render many other Lamps so troublesome, unreliable, and expensive.
